That is what DUPLEXERS are for! Tho, not to radios, on the same band.
they will allow one antenna (multiband) to be used by 2 , or 3 separate
radios at the same time! Comet, and couple other outfits make them.
(for vhf /uhf radios, some with an AM radio port for car radio).

8. Re: Palomar noise bridge

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-01 01:01:10 UTC
From: Jaggy Taggy <outhouse@midcoast.com>
Message-ID: <BE7207D1.7AA1%outhouse@midcoast.com>
Source record: 79870

Richard,

Thanks for your response, this has been very instructive for me.

I indeed run into the problem of a lack of power of the noise bridge. I tried to overcome it by using the 2 levels of pre-amplification on my ICOM R 75 (my Kenwood transmitter doesn't have this feature) to boost the signal. So this was the first frustrating thing.

In addition, the Palomar noise bridge is a tiny, wiggly thing and to adjust for the sharp nulls you are describing is not easy, mechanically speaking, one should nail it to the top of the receiver for added stability.

And then the calibration marks are not confidence inspiring, they seem to suggest that only rough, qualitative measurements are to be expected.

And last my ground is half absent for now, due to the fact that right now it is impossible in Maine to drive a decent copper rod into the ground, once the ice is out I will do just that.

Before I got the Palomar I had built a noise bridge from the circuit of the ARRL Antenna Book and actually got it working, but the calibration process frustrated me and I did not want this insecurity in a testing device I would use to make decisions about my antennas.
Maybe, with your remarks in mind, I should go back and change that design to a higher power noise source to overcome the limitations you described.

I'd recommend anything written by Bill Orr, W6SAI (SK). He and Stu Cowan,
W2LX wrote "Simple Low Cost Wire Antennas" and "Vertical Antennas".

Both are good sources of antenna construction data. They are older texts,
but worth looking for.

73, and good building...

I think that's an old Tri-Ex tower. I Have a Tri-Ex LM470D which looks very similar....the tower sections are almost identical, but the winch, motor mount, and control box are somewhat different. I don't know what the A, B, and C versions looked like. I have restored the LM470D, including remote controlling it in the shack, and it's a good tower. I could copy the manual for you if you'll cover my costs. Let me know if you need more info.

One DOES wonder if the gent that cut me off the other day is an example of
the good trucker or otherwise. On that day I was driving the speed limit
(60) when a truck began to tailgate me. When traffic cleared, he snatched
the truck to the right lane, passed, blew his airhorn at me, and cut right
back in front of me. Now just what the hell am I supposed to do? Get a
ticket to please him? Not a chance! BOTH groups, trucks and cars, are
responsible for plenty of wrecks simply because they aren't paying
attention, going too fast, or too fast for conditions.

Thanks, Everyone, I've printed the list, and am checking them out now.
I'm lucky in that I have access to a good university engineering library.

The odd thing is I did a search on Terman already, and they have his
"Electronic and Radio Engineering" at every branch campus, but not where
I'm at!! 8^(

First calculate P = Q / (R + S)

where

Q = K * Ln(4 * H / d)

R = K * Ln(4 * H / D)

S = Ln(D / d)

and

K = permittivity of insulating material.

H = height of wire above ground.

D = Diameter over insulating material.

d = wire diameter.

All dimensions in same units.

Now P is the ratio of wire self-capacitance with insulation, to wire self-capacitance without insulation. It follows that -

VF = Squaroot(1 / P) is the velocity factor along the insulated wire.

With ordinary antenna wire insulated up to twice the wire diameter with PVC, the reduction in velocity from the speed of light is insignificant and pruning can be forgotten about. It is much less than the pruning sometimes done for end effect which is usually unecessary anyway.

To detect the effect precision measurements are necessary unless the insulation has a diameter of several inches or more. For the permittivity of the insulation to have full effect it would be necessary to completely fill the infinity of space with the insulating material.

Terman, Brown and Klaus all forgot to mention this in their bibles.

Reg, G4FGQ

The picture has been reformatted as it was originally about
one meg and now it is only 120k. The problem is the slow
modems at qsl.net. One gets what one pays for. I'm considering
doing what Walt did - getting a www.w5dxp.com web page. Does
anyone offer a .ham web page instead of a .com, .org, or .net?

Charlie,
I installed the same antenna a couple years ago; like yourself I took
the time to carefully assemble per instructions and it was sitting
around 1.1:1 when tested (on a 10 foot mast in the middle of the yard)
and saw no change when installed in it's operating location. M2 makes
excellent products & you'll be happy with it's performance. FYI,
shortly after installing it, with my pipsqueak 40 watt radio I managed
a 275 mile contact which is my record distance on 2 meters. Wish you
lot's of enjoyment with your new toy!

Hi Buck,

You may have noticed the vacuum of response - most have already seen this movie and skipped out. However, for your benefit:

Like any small antenna, narrow bandwidth. Like any Hi-Z antenna, very skitterish. Like any small antenna, lower gain.

For a helix standing roughly 4M tall for 40M band (which isn't particularly short) under an 8 spoke top hat 6M wide, this exhibits a drive point Z of 40000 Ohms. Put 100W into it and you will see 2KV at the connector. That should take care of grass growing nearby.

EZNEC boldly announces there is loss, and the best gain is -2.6dBi.

The bandwidth spanned from 7.18MHz to 7.25MHz.

From there it is only a matter of adding the critical matching section.

OR

Throw away the helix and use a straight support, shorten the 8 spoke top hat to 4M wide and the drive point is an easier match at 13 Ohms. No lethal voltages at the drive point, lower loss, more gain (albeit of 0.65dBi), more bandwidth 7.14MHz to 7.4MHz.

Still reduces to it's hardly worth the effort to change from one to the other, but all the signs point to a better implementation without the air cooled wire wound resistor. If you want to keep a coil in the picture, you can put it in the conventional place, shorten the top hat spokes yet some more, and find no more gain, and less bandwidth.

OR

Buy an SGC which proudly proclaims it will match a wet string.

OR

Throw away all this folderol, and build a full size antenna (roughly twice as tall as these gomers). No matching issue, bandwidth up the kazoo (7-7.5 MHz), no appreciable change in gain though (in other words, that imperceptible 1dB delta).

All modeling performed using "Real/MiniNEC Ground" (not usually my choice, but then no one else has stepped up to the bar).

OR

Go watch a movie you haven't seen before, it may have a surprise in it.

Chuck W. wrote:
"I`m wondering what is the best practice for connecting two tranceivers to a single transmission line / antenna,----?"

A "circulator" is the device to route the right energy to the right destination among multiple input/output devices. It is composed of line segments in multiples of 1/4-wavelength of transmission line or waveguide. I made one of 600-ohm open-wire line to parallel two 50-KW shortwave broadcast transmitters to one antenna and a dummy load in case of upset. Both transmitters were excited from the same oscillator. It worked well and there was no upset. I didn`t need the dummy load. The circulator is sometimes called a "rat-race". In any case, I swear that they work.

Microwave repeaters are often equipped with waveguide ferrite isolators which allow energy to pass through in one direction with almost no loss but which absorb rf power in the opposite direction. These make clever use of "Faraday" rotation of the plane of polarization as the microwaves travel through a ferrite slab lying in a magnetic field. These ferrite sections allow the transmitter energy to reach the antenna but not reach the associated receiver input of the repeater, so it won`t be overloaded, desensesitized, or accept power which would be better spent in reaching the next repeater.

With ferrite isolators, energy can be routed almost at will. I am still embarrased when I recall dropping an isolator in Motorola`s Chicago plant 45 years ago. The ferrite shattered like glass. They cost several hundred dollars each at the time. The Motorolans graciously said to think nothing of it, it happens all the time. Well I don`t drop valuable stuf every day. If I did , no one would let me in! , unless I was going to spend a few millions, which we did.

I think you can probably use a "rat-race".

Best regards, Richard Harrison, KB5WZI

Hi Brett,

Catch a particularly interesting movie? A good one for programmers
from Argentina: "Una Sombra Ya Pronto Seras" comes to mind. However,
in a diverse crowd at the end of the road and for those willing to
truck 2 tons of nitro over the Andes: "Le Salaire De La Peur."

For Art, all of this is like sitting through "The Saragossa
Manuscript." ;-)

Hi Mike, you've recieved some very good recomendations and I would add to your list one that strictley speaking is not an antenna book, But has some very good info that some of the other books do not carry in it's format. and that is Low Band DXing by ON4UN. It has a good section on Antennas for the Low bands.. and some of what is there can be scaled to higher bands. (But If you can only get your hands on one book Kraus' Antennas is worth the price. Good Luck in your quest. Also no one that I saw mentioned Carr's book Antennas .

Hi Richard and thanks for the definitive comment (short lead issue).

Yes, the problem manifests on the AM radio as well. We are going to do a ground analysis when we do the new wires...I might note, however, that this car has been ignition noisy from day 1 (I got it with about 11,000 miles on it). I was quite disappointed when I first used the AM radio. FM is not as bad, but it is still discernable. It is VERY obvious on 2m FM, not so much so on 440 FM. I do believe the problem has gotten worse over time and right now it is "unacceptable", which I hope will help us isolate it.

I'm familiar with the "ground window" concept (SPG) and will take a look at the quality of the grounds (we plan to remove and clean all the obvious ground connections, especially the main/heavy ones around the battery.)

I'll let you know how things turn out when we work on it next week after the new wires show up.

Thanks for taking the time. 73

Dear Mike:

A "must have" is the ARRL's Antenna Handbook. When you find yourself desiring to know the rest of the story, Kraus' "Antennas" is the book. It is as lucid as the author was in person. The third edition has some proofreading issues that most people will not notice, but if you start at Chapter One and follow along, you will understand. A few latter chapters specialized on a single antenna type that you might not be interested in, but that will be apparent. A soft cover edition (International Edition) exists.

I still hope to live long enough to find a copy of La Port's book. If you find more than one, please let me know. The book contains some engineering aspects of serious antennas not otherwise available.

Enjoy! 73 Mac N8TT

MFJ used to make the 1700B -- it's been discontinued, but maybe you
can find one in remaining stock somewhere -- it handles up to 6
transceivers and 6 antennas, you can mix or match in any manner. It's
a manual switcher, tho', not automatic.

The wire insulation they had in Ternman's day wasn't too good but expensive
so who in their right mind would use it for an antenna.

I agree 100%, it's not worth worrying about - if all I wanted is to get
a 20M dipole running on the air. But that's not my point. I'm trying to
use dipoles to determine the velocity factors of insulated wires used
for the radiators.

> Another 'speriment to try: build a fairly wide-spaced two wire

> spacings will show more effect than wide.)

Now we're cookin', I like it, this approach has definite appeal and I
need to explore it for several reasons. First because of the sharp
nulls, it takes out the coax and it's a simple sort of "bench test" I

can do at ground level. I'll build three identical shorted 20M or 30M close-spaced quarter wave lines. One with bare #14 stranded wire, one with the insulated #14 THHN wire I usually use for quick & dirty dipoles and one with The Wireman's very flexible #544 or #546 #14 insulated PVC jacketed wire I'd use to build a hex wire beam or a quad.

Then I'd use a grid dip meter to find the resonant frequencies of all three. I'd use an HF rcvr with a digital freq display to listen to the GDO rather than trust the GDO dial calibration and resolution. Yes?

Which leads into another head-scratcher I've had in the past. I've had a bad time coupling a GDO to quad elements because it takes a couple turns of wire near the GDO coil to get enough coupling between the quad element and the GDO. Which in turn means that I've shortened the element length and the result is wrong.

What's your suggestion on a method to accurately measure the resonant frequencies of the quarter-wave lines in this exercise?

Thanks,

> Cheers,

Hi Brett,

How many screen names do you have? Is your serial multiple
personality somehow better than what you see as parallel multiple
personality? What about false personality? What you perceive as a
talent in yourself is projected to be the mark of a fool upon another.
In this group, we observe the laws of what are called symmetry and
reciprocity - two very strong, scientific principles.

The responsibility of posting to a newsgroup is that only you choose
what you think is important to discuss. Of your choices to go
technical or metaphysical (or CB truckers), I have no control over. I
have responded to your technical comments and your sidebars (as now)
equally.

Upon my analysis of the Top Hat on J-Pole you could have acknowledged
the results, asked questions about particulars of implementation, or
challenged the results to greater scrutiny - and simply ignored side
topics. I observe you have not shown any interest in obtaining the
model used. We share models as a commonplace expectation of peer
review. Any of this would have constituted technical correspondence.

Instead, the side-topics attracted your notice and you took that route
instead. I welcome all correspondence, but I am not responsible for
what you respond to when there are choices - especially when you can
add topics as well (a privilege I exercise, you present above, and I
do not object to in anyone).

So, as I offered so long ago:
1. Adding a coil offers loss [demonstrated];
2. Physical size in relation to wavelength dominates launch
characteristics [demonstrated];
3. It barely matters [less than 1dB].

The launch gain of a half wave radiator did not appear simply because
a much shorter antenna is ginned up to be antiresonant [demonstrated].

This also returns me to an unanswered question (also technical):
>>The rubber duckie antenna is certainly useful for some situations, however,
>>it is better if it stays on the walkie-talkie and we use another design for
>>portable or base use.

>Given this opprobrium, what makes its cousin for 20M more suitable?

OR

I am both content, and competent to discuss those movies that would have been more enjoyable than the alternative of sitting through the snooze of finding gain from a small antenna.

OR

I am content discussing how to obtain the most gain from a small antenna, or simply pointing you at 300 pages of results I've done years ago.

Got to the library today and read 250, 800, 810 and 820. Interesting section in 810 that effectively requires all Ham antennas to be 14AWG or greater. Makes products like Wireman's 18AWG copperclad steel a nonconforming wire for antennas.

I was planning to use the 18AWG for my 88ft center supported doublet. The unsupported length would be about 50ft. The NEC is pretty coarse grained at "anything less than 45meters".

Did I misread this? Makes "stealthy" antennas pretty difficult.

Section 250 is pretty opaque on grounding and bonding. I came away with the impression that they wanted ground rods (8ft) every six feet. Did I misread this as well?

OK, I admit to being a spoiled brat when it comes to making measurements like this. The easiest for me would be to set up a network analyzer, with the analyzer's source and receiver each coupled lightly to the line. But there are other ways. You may not even need a signal generator. You could loosely couple a receiver to the line, and loosely couple an antenna to it on the other side, and as you tune the receiver across the resonance, you should notice a sharp peak in atmospheric noise. With a loaded Q of a few hundred, the peak at 10MHz would be a very few tens of kHz wide. You could also build an oscillator which uses the tuned line as the frequency-determining element, and just count the frequency of the oscillator. A simple version of a network analyzer could be done by lightly coupling an RF generator into the line, and putting an RF detector across the line a small distance up from the shorted end. I'd use either a simple diode detector, which can have pretty high input impedance, or one of the Linear Technology or Analog devices RF detectors, but since those are lower impedance, tap them down very far on the line. -- I'd expect a 10MHz quarter-wave resonator made from 600 ohm line using AWG14 wires to have an unloaded Q around 350.

You can achieve that loose coupling by calling the center of the short across the end "ground" and tapping up just one or two percent of the length of the line from that for the "hot" connection. Or you can couple in with a loop, say of a diameter about equal to the line spacing, held next to the shorted end of the line. "Reference Data for Radio Engineers" shows various coupling schemes in the "Transmission Lines" chapter. As long as you keep the coupling light (to keep the loaded Q high), and are consistent in the way you arrange things, you should be able to measure the resonance to within a fraction of a percent repeatability, if not absolute accuracy. Relative measurements should be all you need in this case. And I assume it's obvious that though the resonant line will not have exactly the same VF as an antenna, as you increase the wire spacing, it should approach the same

effect as you'll see in the antenna. Then compare with the formulas Reg posted, and if you see significant differences, try to resolve what's causing them.

By the way, one place where the "velocity factor" effect might be noticable is in parasitic elements of an array in which you're trying to achieve maximum gain. The element tuning will affect phasing among the elements and therefore gain. If the design is narrow-band, high-gain, you might actually notice some effect from the insulation.

Cheers,
Tom

I'll second Richard Harrison's recommendation of King, Mimno and Wing. King wrote the "Antennas" chapter, and I especially like his careful wording that makes the premises on which the rest is built crystal clear.

I'd also recommend an article that appeared in the April and May 1977 issues of "Ham Radio" magazine. It's "The Antenna-Transmission Line Analog" by Joseph Boyer. It's good for understanding impedances along linear wire antennas (dipoles, and verticals fed against ground planes, for example); if you digest it, you should be able to do an accurate back-of-the-envelope calculation for a loading coil to resonate a short antenna, placed any reasonable place along the antenna, for example. It starts with a view about how fields are developed in the vicinity of a linear antenna. It can be a bit difficult to find, but I've been known to send scans or photocopies of it...

Cheers,
Tom

I've been comparing the results for an antenna I modded [1] with the demo version of EZNEC and 4NEC2. Although EZNEC warned that the segments were a little long measurement with an MFJ analiser shows a good match with the predicted results. Being naturally tight I thought I'd try one of the other modeling programs 4NEC2 which allows more segments. However I noticed a discrepancy of about 1dbi in the predictions and a different predicted SWR. These differences remain even when the 4NEC2 model is constructed with the same number of segments as the EZNEC version and both models using no ground (free space).

As both models are offering results to 2 decimal places I would expect to be able to trust them to 1dp. Am I just kidding myself that modeling is this accurate (Ignoring all the real world variations)?

Hi Rod,

Usually the difference lies in the modeler (the loose nut behind the steering wheel).

Do both models have the same diameter wire/rod for elements? Do they both observe real world (copper/aluminum/aluminium) losses?

68. Re: Variation in modeling predictions between software

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-01 21:10:44 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <114re6lgjchs52b@corp.supernews.com>
Source record: 79732

Never confuse resolution with accuracy. The two decimal resolution provided by EZNEC is sometimes useful in detecting which way the gain is going when making changes. It's not meant or claimed to represent the accuracy of the results. You should never expect accuracy of a model to be within a hundredth of a dB, or anywhere near that. And I seriously doubt the possibility of measuring an actual antenna to that accuracy. In a lot of cases, 1 dB is pretty good for either modeling or measurement.

EZNEC, and I'm sure 4NEC2, uses NEC-2 for calculations. Both should produce results essentially identical to NEC-2. (I say essentially, because at least with EZNEC, there are always minor differences due to such things as consolidation of constants scattered around the original code, differences in calculation order and variable precision, and so forth.) In general, if a model can be constructed that's identical to the real antenna and its environment, the results will be strikingly good. But that's not always possible. And there are a number of situations where NEC-2 and therefore EZNEC does have difficulty producing a good answer. One is when wires of different diameters are connected together. This is covered in detail in the EZNEC manual (integral to the demo program as well as the full programs) -- see "Stepped Diameter" in the index. Other problems are often related to source placement, which NEC-2 is very fussy about. These can sometimes be fixed or corrected for, but sometimes not. The Average Gain test (see "Average Gain" in the EZNEC manual index) allows you to spot and correct for those kinds of problems.

The most common cause of reported discrepancy between EZNEC and NEC-2 and some other programs is that in EZNEC, you specify wire diameter while for NEC-2 you specify radius. People often miss that when comparing the two. Another common cause of differences -- not present in your situation -- is when analyzing antennas near antiresonance (e.g., half wave vertical or full wave dipole), small changes in source placement cause large changes in feedpoint impedance. In those cases, differences in segmentation can produce substantially different impedance results.

I have never seen a significant difference between EZNEC and NEC-2 results (except where I've unintentionally introduced an obvious bug into the modified NEC-2 code incorporated in EZNEC), and it's my intent that there not be any. I'd like very much to hear from anyone who thinks he sees a difference. So far, all apparent differences have turned out to be due to unintentional differences in the models, but if any real discrepancy is present, I want to know about it so it can be tracked down and corrected.

You seem to have a problem with my name...

Would what I say have more importance to you if my name were "George Walker Bush?" How about "Princess Dianna?", "Lord Balder Wash?" How about an alcoholic PhD. down on his luck--Edward Noble, PhD., in the gutter?

Is a rose not still a rose by any other name? Is logic not still the same logic no matter who speaks it?

I have hoisted the pirate's flag in rebellion of fools who place importance on bloodline, circumstance of life or the self-importance of their being or--even for the sake of control alone--BUCKO!

However, instead of a skull and bones, the symbol on my banner looks surprisingly like--JOHN SMITH!!! (who was that masked man anyway? (hey, that voice sounded like Tonto!)--well, maybe it looks even a bit like Alfred E. Newman!

I'll tell ya what, pick a noble sounding name, the sound of which inspires shock and awe in those who fall victim to my speech--I'll change my gmail account for you....)

You have already tempted me to replace my Russian made "California Kilowatt" (well, 5.5 KW--but it is hard to get true linear performance at reduced input power and drive <grin>) and "keenwood", with a 6X2 push pull in parallel, 1500w+ Chicken Band linear! And, that 225 amp 13.8 v power supply gets hot when I just think about a key down! (the sound of all those cooling fans are annoying, don't cha think?) Somewhere in the attic is an old Johnson 11 meter with increased output to drive the 1500!!! I can hear the "Anyone got a Radio Check", "Break channel 19", "10-4 GOOD BUDDY", "AUUDDDDIIIIIOOOOO!" and "What's up ahead southbound?" coming off the 11 meter band now!--it brings a tear to my eye I tell ya, the memories.... and the ham bashing sessions we used to engage in---felonious I tell ya!

My only fear is the feds detecting me by the strange purplish glow emanating from my antenna, while I kick back and shoot skip--sipping a Corona...

But then, I am NOT normal--I like to have my bit of fun...or, at least I did in the past...

If your test of intellect is whether one agrees with you or not--or, whether someone plays your game of insane obfuscation--or whether one withholds his/her identity for protection from the insane (however, I did just indulge you a bit, didn't I?), or whether one "used to be"/"still is" a part-time "Chicken Bander"--I have failed, be prepared for the masses which will follow...

Now, with all this talk about velocity factors and the calculation thereof, one should consider the possibilities of and consequences resulting therefrom of velocity facors in the range of positive numbers greater than one.
With these velocity factors, some hams would be able to hear some signals even before they were transmitted, giving him the time to adjust his rotor, his antenna tuner, and his hearing before the signal arrives.
If the signal leaves the antenna before its transmitted, then the concern over impedence matching would be for naught.

Hi Dave,

This was reported some time ago. One of the key properties is the construction of a flat media that could focus light to an absolute point instead of an area. I don't think they mention this at your referenced page.

I've played with the models, but have still some way to go in this segments intensive hog.

Jim, the NEC, in states that have adopted it, does not regulate low voltage systems or antennas or comonents thereof, beyond (varying interpretations) of the first bonded ground system. NFPA-780 Standard for the installation of lightning protection systems DOES apply best practices beyond that point, and yet it is not actually code. But it is referenced and for all practical purposes, becomes code where referenced in NEC. Confused? ;-)

Your antenna may or may not be considered "low voltage" - this rarely if ever comes up in construction permitting btw, but this group could debate it for days. Your antenna system definitely becomes high voltage when afected by a nearby or direct lightning strike. In my unqualified opinion, the two reasons for minimum recommended wire gage, are withstand of high energy from faults or lightning (fire and electrical shock hazard there), and durability of external systems, the failure of which compromise parts or the whole of electrical and lightning safety.

Most of the antenna language you collected are suggestions that are interpreted as best practice. But they are not regulated and it probably should omit comments such as you took somewhat out of context in your example. Where NEC can be applied strictly (or not, again depending on your state) is where antenna feedlines traverse inside spaces of dwelling, commercial or industrial structures, and antennas attached to roof systems, wall systems, interfaced with ground systems, etc. In those circumstances, the possibility of death, serious injury, and severe property damage is a real possibility where improper methods of construction would be allowed. Minimum air-spacing in walls/attics is one example of that requirement.

> misread this as well?
>

> tnx
> jtm
>

I think you did, yes. The relevant part of art.250 to comprehend, is the use of bonding in both electrical safety and lightning protection. In electrical safety, the purpose of bonding = fault clearing by low impedance path to the circuit breaker, NEVER by providing a circuit path to earth and earth-to-circuit breaker as the path to clear the fault. This is where 99% of hams go astray, mostly because the daunted organizations of their societies say grounding an amp, etc (to earth) will save their life. Wrong! One radio engineer here, who I think is quite brilliant in those areas, thought a ground-to-earth protected people, when in fact it could kill. This is no doubt due to massive misinformation in the amateur world about basics of electrical safety, as there is also about lightning protection.

Back to your ground rods - you should never modify or provide any electrical grounding system for your high voltage AC system in a residence. Licensed electricians are required for that. Your work will be related to grounding and bonding an antenna system (including feedlines) to the mains electrical grounding system, and that should be inspected but rarely is.

Your ground rods should be at least their sum's depth apart, and should be sunk a minimum of 10' in the ground (or 3' deep if laid horizontally), or the required number of feet in a UFER ground (bonded reinforcing rod in poured concrete). 16' ("conductor" sum's depth of two 8' ground rods sunk 10' deep) is generally considered the separation standard you questioned. It is described in great detail in NFPA-780.

I really applaud your actual work in the library on a subject too boring for most radio enthusiasts to spend much time on, even though their very lives (and others around them) could depend on it.

Hello All:

Looking for a few hundred feet of RG393 coax.

This a coax about the same size as RG213, 9913, or LMR400 but has a silver plated stranded center wire, with Teflon dielectric and a double silver plated shield.

Working a old aircraft restoration project. So also interested in cable clamps.

Jay in the Great Mojave Desert

Let's start a parallel thread on the effect of coating a 14-gauge
antenna wire with a thick layer of ferrite. Say 1mm thick,
permeability = 100.

Would this have any effect on velocity factor? If so, by how much?

Reg

a.yes
b. don't know

Perhaps you could look at it from the point of view of an increase in
the inductance per unit length. Or else model it with a 3D E-M simulator.

I wouldn't trust an RF-sensed switch to do the job (have never seen one anyway). The antenna jack on the rig that is NOT to be used would have to be grounded first before allowing the primary rig to transmit. A bit of a dilemma. You can use a manual coax switch (which grounds the unselected outputs), but even then quite a bit of signal is coupled to the transceiver who's connection is grounded. I tested this setup on HF, bringing the power up slowly on the selected rig and tuning the unselected rig to the same frequency. On 10 meters, the signal present on the unselected rig's input was enough to cause a 45 dB over S9 signal. Not enough to damage the frontend in this case, but you'd need to test the switch you're planning to use to see what results you get.

Hi Jack

Thanks for the clarifications. The NEC 2002 book was a reference book and required just sitting there and reading it rather than checking it out. FWIW, there isn't much "context" on the antenna requirement other than the blanket assertion of wire gauge vs unsupported span. I find it interesting that 18th edition of the ARRL Antenna Book also references this same NEC section then goes on to mention in another area of the book how to use finer gauge wires to make stealthy antennas. Right hand not knowing about the left hand???

As you noted I wouldn't dream of modifying the electrical ground system of the mains of the house. I'm only going to put a little parade of ground rods on the path to the mains ground rod and daisy chain them all together with #2 with a pair of clamps on each rod. It will only take two additional rods to get around the corner and up to the service ground. I'll have to dig down to get to it I suppose.

There will be one ground rod out under the antenna feed drop in the woods where the ICE unit will be directly mounted on the ground rod. The tuner will also be located there after the arrestor.

>From there the RG213 and control line from the tuner will run underground about 60ft to the house where they will connect to the shack ground rod just outside the window. The single point ground inside the shack will drop out to this rod on about a 4ft run of copper something. It's this ground rod that will connect to the other two and finally to the service ground via the #2 daisy chain.

Coax (RG8x) is used to enter the house from the ground point so that shouldn't be an issue per the code.

Since the antenna wire is actually out in the woods and 60ft or more from the house I'm going ahead with the 18AWG copper-clad steel and not worry about it.

I've got everything I need to finish this installation except the ICE unit which is supposed to arrive today. Fingers crossed...

tnx
jtm

Why not start with an insulating material like Teflon?
That's what the previous discussion was about. Given
the dielectric constant of Teflon and the thickness,
EZNEC+ 4.0 will take the VF into account.

Something easier for me to do was to take the 20m dipole,
DIPTL.EZ, that came with EZNEC+ 4.0, remove the transmission
line, and determine the resonant frequency for uninsulated
wire and for wire insulated with 0.1 inch of neoprene with
a dielectric constant of 6.7 (deliberately chosen to emphasize
the differences).

The resonant frequency for uninsulated wire was 14.42 MHz.
The resonant frequency for neoprene insulated wire was 13.3 MHz.
That is an abundant amount of insulation with a high dielectric
constant and it lowered the resonant frequency by 7.8% according
to EZNEC.

Adding the insulation increased the feedpoint impedance from
57 ohms to 65 ohms which means the forward and reflected
waves on the standing-wave antenna were attenuated more
using insulated wire and sure enough, using that particular
insulation reduced the EZNEC maximum gain by 0.12 dB.

Many people have noticed shifts in resonant frequency when
their antenna gets wet. Water has a dielectric constant
around 80.

You should be good to go Jim. You might not have to scratch far to find the AC mains grounding electrode. Depending on when your house was built, it could even be a cold water pipe ground. If it is a rod, it is probably not buried deep at all. The 10' rule is recent and not followed in most residential cases anyway. When a local inspector arrives to approve a contractor's installation, he is checking only for a 25ohm or less grounding electrode. If the contractor cannot achieve 25 ohms or less from one electrode, the code requires he sink a second electrode. And nothing else. That's irony, huh?

Best regards,

Jack

There are various models of those in my dealer book. The "Z" isn't listed, I've never heard of them being connected any other way than 50 ohms. Someone can correct me if I'm wrong - as I'll too learn something. As to radiation pattern, if they're stacked, it is one value, offset - another. As to "how much gain", depends on the model and again, if stacked or offset.
If you had a model number, I could be a bit more specific. The gains of those I handle are anywhere from 2 dB and up.

Hi guys.

I am putting up a K9AY loop receiving antenna. I will have about 300' of cable going to it. As I understand it, this cable should be buried for best performance.

Any suggestions on what cable to use, for both control and signal? Looks like 6-18 rotor cable will do for control, but I wonder about burying it.

In his book _Ferromagnetic Core Design & Application Handbook_
Doug DeMaw claimed to have put ferrite sleeves on a vhf dipole
which reduced its size without introducing significant loss.
He claimed to have cut the size of the dipole in half.
You'll have to do the same thing yourself if you want to know
whether or not he was right.

I live in the woods in Maine and I wouldn't want to disturb the looks of this landscape with a tower, so I am using my trees.

I choose some large pines which do get me 50 + feet in the air and I install folded dipoles, one for each band.

To get up there I bang 12" galvanized spikes where I need them as permanent steps. Of course to get up there the first time I use an old construction safety harness attached to a belt which goes around the tree. This allows me to lean back, scary! , and nail, you can't get a nail in while holding on with both hands...

Pines in the woods do have very few branches down below, they just go high for the light, and the branches which I encounter, mostly deadwood, I cut off.

So I create a smooth pole topped, way up there, by the crown of the tree.

Once up there I install a pulley and a piece of 1/4" rope and descend.

Everything else happens from the ground. I lower the rope, attach the antenna and up she goes. Should maintenance be necessary the whole antenna comes down the same way.

The tree doesn't need any support, it has been around for 50 to 100 years and is just doing fine.
The nails, quite a few, do not seem to disturb them, at least I don't notice anything and I have been using trees in this fashion for quite some time.

You can tie one side of your antenna off, the other side gets a heavy weight which goes up and down the tree during storms etc.

I am happy to live on a piece of land with several hundred radio towers which maintain themselves.

Hi all,

First, sorry for my bad language : English is not my mother language...

I would like to build a 4�l quad 5bds (10/12/15/17/20). I have only 1 plan of the antenna. I'm looking for others plans to have several ideas and to compare the differents schemes.

On the plan I have, the lengths of wire are to phone portion. I do CW mostly. If I lengthen the wires few centimeters (knowing that a quad have a large bandwith), spaces between elements changes ? I don't think... because we can adjust the reflector with a according loop. What do you think about it ?

I'm taker of yours ideas on this subject.

Thanks beforehand...

Regards

GG

interesting.
if coating the antenna with ferrite can reduce its size,
would ferrite sleeves over the ferrite sleeves reduce the size even further?
we're always looking for ways of reducing the size of our dipoles.

Yea, but isn't that the same thing as winding a helix to increase the
inductance per unit length to accomplish the same results. I don't
know if Doug was right, cause I have not done either. May try it.

Balanis, in his book _Antenna Theory, Analysis and Design_, has
a short section dealing with this. Define a parameter
Q = (mu - 1)ln(b/a), where mu is complex permeability of
the ferrite, a is the radius of the conducting wire, and b is
the radius of the conducting wire plus the ferrite. According to
Balanis, increasing the real part of Q "a. increases the peak input
admittance b. increases the electrical length (lowers the resonant
frequency c. narrows the bandwidth." In order to use this formula,
you have to know the complex permeability of the ferrite coating.
I don't know how you'd measure that. Maybe Richard Clark knows.
It would be fun to try. I wouldn't pin any hopes on it being

practical, though, since it doesn't seem to be in general use anywhere.

If it's a dimmable lamp (triac-type dimmer) it could quite easily put
out RF hash which might interfere with HF operations.

If it's non-dimmable, I think it's no more likely than an ordinary
incandescent fixture to emit RFI.

Dimming a halogen bulb is a bad idea, really - it can greatly shorten
the life, because the tungsten/halogen scavenging cycle doesn't work
well (or at all) at lower filament temperatures.

Source record: 79626

You can measure the complex impedance of a ferrite core quite easily and with moderate accuracy using an antenna analyzer. From that reading and a low frequency impedance measurement, you could calculate the complex permeability. However, you can find graphs of the values for common ferrite types at http://www.conformity.com/040spotlight.pdf and other web sources. But it's not obvious to me why you'd need to calculate or measure the complex permeability -- all you need to do is measure the impedance of a short wire with the core slipped over it. When you slip the core over the antenna, it'll behave just as though an impedance of that value was inserted in series with the antenna wire at that point.

Different types of ferrites are quite different at HF. Low frequency ferrites like the Fair-Rite 70 series are primarily resistive at HF, and would simply add loss to an antenna like adding a series resistor. High frequency types like the 60 series are inductive with reasonable Q through the HF range so would behave pretty much like a series inductor of moderate Q. Type 43, probably the most common type now available, has a Q on the order of 1 at HF, so it also would primarily just add loss to an antenna.

But hey, if you use one of the lossy ferrites you'll end up with an antenna that's really broadband and quiet. That's what we all want, isn't it?

Roy Lewallen, W7EL

Hi Tom,

I've measured a number of ferrites, but only in the HF region. They
do show a range of values, with most of them not very reactive (in
relation to the R).

Below are some tips from the Ramsey Electronics site on improving
atomic clock reception

bob
k5qwg

If you have a desk top unit, try rotating it 90 degrees. If
you have a wall clock try mounting it on a wall perpendicular to the
one it is currently on (e.g. if it is on a north-south wall try a
east-west wall). The antennas are directional and you might be able
to improve the signal strength by turning the antenna.

Place the clock along a wall or near a window that faces
Colorado.

Locate the clock at least 1 or 2 meters away from any computer
monitors, which can cause interference (some monitors have a scan
frequency at or near the WWVB carrier frequency of 60 kHz).

If you are in a strong interference area, or in a highly
shielded location you might not be able to receive the 60 kHz signal
from WWVB.

Floyd Sense wrote:
"I wouldn`t trust an RF-sensed switch to do the job (have never seen one anyway)."

They abound. Plenty of devices are keyed when RF is sensed. Catastrophic failure can be avoided by secondary protection for more security.

If simultaneous operation of two or more devices with one antenna is required, switching between them wont work anyway. Some form of combiner is needed.

A device for automatic switching is the duplexer used with RADAR which automatically switches the antenna from receive to transmit at the proper times.

A diplexer, on the other hand, is used to combine the picture and sound transmitters to the same TV station antenna. This may be a bridge circuit or something similar. Its purpose is to isolate the transmitters from each other while feeding the same antenna.

That was also my goal in combining the outputs of two shortwave broadcast transmitters to the same antenna but they were of the same frequency and phase.

The circulator I suggested in an earlier posting is a variation on a device described in a couple of books I used to have on amateur radio repeaters. In my case I wanted to make a 100-KW transmitter from two 50-KW reansmitters. It worked well.

The medium-wave broadcast plant I worked in, with 950 KHz and 1320 KHz transmitters, accessed the same tower through frequency pass / reject filters in the coax lines to each transmitter from the same antenna. It was no problem, given the frequency separation between the transmitters. An amateur VHF repeater has a much more serious problem given a much smaller percentage frequency separation between its receive and transmit frequencies. The amateur repeater nust often use cavitiesto separate the frequencies enough..

Best regards, Richard Harrison, KB5WZI

No RF problems. Halogen lamps have tungsten filaments (like normal
incandescent lamps).
The difference is that they are filled with halogen gas, which allows them
to last longer and glow a bit brighter than their normal incandescent
cousins.
The tungsten in regular lamps slowly condenses over time into a darkish
coating inside the bulb which cuts down on lumens output. The halogen gas
prevents this, and results in a little brighter lamp for a little longer
time.

The 'HID' High Intensity Discharge lamps may be the ones you're thinking
about that may give some RFI.
Mercury Vapor, Metal Halide, and 'HPS' (High Pressure Sodium) lamps fall in
this category. They all use ballasts.

I must say the Roy has best discribed the differences as in the way the program is designed to calculate along with the correction factors and other features that are added.

My experience in selection has been to try the difference software to model simple yet similar models to my final intended, using the samples provided by the designers and compare the results. The one that provides the best results in terms of real life application (actual antennas) compared to my modelling is the one that I use, as it best suited for my modelling (input method) applications.

Additionally you should go to www.cebik.com, the site contains a discription of the different modelling software available and the advantages and disadvantages of each.

Enjoy,

I just put in a set of under cabinet halogen 20 watters ..... boy what a bunch of crap RF wise. There is a 12 V supply that virtually eliminates the AM band and somewhat less on HF. This is at distance of 20 plus feet. Of course they were made in Hang Chow ... no doubt somewhere east of Ft.Wayne.

I've done this and it works fine in the right situation.

Just take two resonant antennas on whatever frequency you want, aim
one towards the repeater and the other towards your house. Connect
them with good coax as short as possible but the length must be a
multiple of 1/4 wave at the desired frequency.

Not a fancy solution to a problem but it can make the difference
between being able to work the repeater and not even hear it.

Another solution I've used is to bounce the signal off of somehing - a
big billboard or piece of plywood is a good example.

Anyone work with the gamma-match to the point of becomming a guru?
I am looking for "Everything you wanted to know about a gamma-match--in a nutshell."
In other words, what set of formulas would give you length, conductor spacing, gamma capacitor value, ratio of gamma rod to driven element diameter, and a starting measurement for the shorting bar between conductors-- for a given frequency?
What conditions requiring a match is the gamma best suited for?
What would need to be taken into consideration if one is using the match on a monopole? A dipole (T-match version)? A driven element in a yagi? A loop?

Tom, I have the same awful interference from new under-cabinet halogens. Similar to your report, mine create terrible interference only through MF, and limited hash on HF also. Mine are at least 40' away, and the station power has its own load center/branch panel. The lamps are the switchable 2-level (not variable) and interference is present both settings.

I noticed a brand of halogens at Home Depot (now, of course) that state "No Radio interference". Figures.

I suppose the plasma looks like a DC resistance over a region of its characteristic and maybe even negative at some point. It depends of course if we are talking about a glow or an arc. With an arc the current discharge is somewhat infinite and the huge noise makes it impractical. I'm not sure about the noise with glow discharge on a long neon tube but I'm assuming it is very low judging from some brief measurements I made on a neon indicator bulb. BTW these make good UV detectors wrapped in aluminium and biased at the conduction threshold. I'm only guessing the long neon tube has a DC resistance of about 50 ohms per foot. Something 30 feet high would therefore be around 1.5K. What are typical running voltages and currents for neon signs? BTW don't know if running 1KW would it make a fabulous light show? Shades of Nicolai Tesla!

My dear friend Cecil,

It's a waste of time mentioning things like DIP.TL.EZ and EZNEC4. Hardly anybody has ever heard of whatever they are. I certainly havn't. And the chances of obtaining them, even if legal, within the next 12 months is so remote, by then, everybody will have forgotten what it's all about and will have lost interest in the subject. So nobody ever takes any notice of references and switches to another more-interesting thread on the newsgroup.

If you have any facts to say then say them. It's up to you to be convincing. If you think you need the support of Terman or Kraus then you lack self-confidence. Bibles are usually misquoted, or taken out of context anyway. Second-hand, plagiarised, information adds nothing to reliability.

As usual, you gave only half of the information needed to make sense.

In addition to a thick neoprene layer of 0.1 inches, with a high permittivity of 6.7, what was the antenna wire diameter and the approximate height above ground?

Without such details your information is old-wives' waffle.

As things are, your velocity factor reduction of 7.8% does not go out of the ball park value predicted by my formula.

My formula takes a few milliseconds to calculate. Whereas your method requires a 4-weeks training course and several hours making the model.

You have the same disorder I do - the stuff you need comes on the
market after you need it 8-} As to the interference, I'll go out on a
limb and say it's the power supply not the lamp - I've hooked up
halogen lamps directly to 12VDC and had no interference. Wall warts
are, as has been mentioned here many times, notorious for RF
interference.

EZNEC will give you ballpark answers that require
some adjustments to length and capacitance. The
free version of EZNEC is available at www.eznec.com.

> What conditions requiring a match is the gamma best suited for?

When your electrical dipole is one piece of metal,
i.e. a physical monopole. The center of 1/2WL of
one piece of metal has the voltage equal to zero
so you cannot feed it there but you can connect
ground to there. Then feed it some distance away
from center through a parallel element and a series
capacitor.

Only if some erroneous statements were made here that I don't recall seeing or if a person doesn't look at the chart carefully.

The chart shows that in the absence of ground loss (the "theoretical" curve), the difference in gain between a very short vertical and 0.25 wavelength high vertical is 0.4 dB (300 vs 314 mV/m). This is approximately the number I've quoted before on a number of occasions (0.45, or less than 0.5 dB). I don't recall seeing anyone here ever claim that this will be the gain difference of real antennas with loss (the other curve) -- as the antenna gets shorter, the radiation resistance drops, and so the fraction of power lost in the ground system increases. The curve clearly shows how strong this effect is when using the ground system adopted by AM broadcasters, and in fact the ground system resistance can be inferred from the graph. This was first described and shown in detail by Brown, Lewis, and Epstein in their classic 1937 paper. Jerry Sevick, W2FMI, built and measured a number of very short 40 meter verticals with elaborate ground systems to show that the loss could be kept very modest in a real installation. His experiments were published in QST in the '70s.

One shouldn't overlook another potentially large cause of loss when using a very short antenna, either -- the matching network. Short dipoles and verticals have a large amount of capacitive reactance which requires an inductor to match, and loss in the inductor can become large compared to the antenna's feedpoint resistance. But like ground system loss, this isn't a loss inherent in the antenna itself.

The actual performance of a vertical can be made to approach the "theoretical" curve arbitrarily closely with a sufficiently elaborate ground system. The system the broadcasters have chosen isn't pefect -- it's simply one that's been deemed to be good enough for the job at hand. Ground systems can be made which have lower loss.

What you have to always keep in mind is that if you put 100 watts into a lossless antenna, 100 watts must be radiated. The lowest possible gain of such an antenna is 0 dBi, which is what you get if that 100 watts is spread equally in all directions. An infinitesimally short dipole has a directional pattern which is similar to that of a quarter wave dipole, just a little fatter. That's why its gain is a little less.

Even though we can't ever build a lossless antenna, it's useful to understand them. It allows us to separate, and trade off as we wish, the various factors affecting gain and loss.

Roy Lewallen, W7EL

136. Gain of Vertical Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-03 18:25:06 UTC
From: Richard Fry <rfry@adams.net>
Message-ID: <4250355b$1_3@newsfeed.slurp.net>
Source record: 79649

The link below leads to a graphic on the FCC website showing the groundwave field strength produced by 1kW from vertical radiators working against a radial ground system of 120 quarter-wave radials; the typical AM broadcast setup. The field strengths in the table do not include the affect of ground conductivity. They are related only to the "efficiency" (an FCC definition) of the radiator against the stated ground plane.

Field strengths in the FCC chart range are empirical values, and range from ~190 mV/m for a 0.05 wavelength vertical to ~641 mV/m for a 0.625 wavelength vertical. This is a considerable range of field strength values for matched, simple antennas all driven with the same tx power.

Statements on this newsgroup about the free space gain of a very short doublet antenna being not much less than a full-size 1/2-wave dipole might lead some people to conclusions different than shown in the FCC chart.

"FWIW."

The input impedance of a 0.05 wavelength monopole, over a perfectly
conducting ground plane, is
0.836 - j1331. Using a shunt "L" series "C" matching network -- inductor Q
of 300 -- indicates a
network loss of 9 dB.

EZNEC is available in a free demo version from www.eznec.com
You can enter dielectric constant and thickness of insulation.

> If you have any facts to say then say them. It's up to you to be
> convincing.

I once replaced an uninsulated loop with insulated wire to
try to reduce wind static/noise in AZ. The resonant frequency
went down by about 200 kc on 40m.

> As things are, your velocity factor reduction of 7.8% does not go out
> of the ball park value predicted by my formula.

Maybe I misunderstood. I thought you were saying insulation
has no effect.

> My formula takes a few milliseconds to calculate. Whereas your method
> requires a 4-weeks training course and several hours making the model.

Some training is worth it. My training using ELNEC and later
EZNEC has been very valuable. I certainly wouldn't spend "several
hours" on a model only to report the results in one thread on
this newsgroup. That's not enough return on investment. It took
me about seven minutes for that last report.

143. Re: Gamma-Match formulas--design?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-03 20:24:27 UTC
From: John Smith <assemblywizard@gmail.com>
Message-ID: <d2pje0$1de$1@domitilla.aioe.org>
Source record: 79657

I am sorry, I abbreviate my questions and think everyone psychic and will know what I am thinking, it is a fault of mine, many have pointed it out to me, I am working on correcting it (progress, as you can tell, has been slow)... let me attempt to correct my error.

I am sure EZNEC is an excellent application. But with such applications, you spend your time learning the application, rather than the underlying principals; it requires you to structure yourself to fit the program. For my hobby efforts with antennas, I would rather just learn and possess the skills and do the calculations and design myself (I am rather eccentric this way.)
Learning to rely on EZNEC I would just remain lazy and dependent on it and, un-knowledgeable to the math workings and methods underneath it.

Since my son graduated college, I inherited his old "TI-83 Plus" programmable graphing calculator. I was looking more for the actual formulas and design methods to plug into the calculator--I would simply translate them to basic language (maybe later assembly, its' a Z80 processor.)

The "Monopole" I had pictured in my mind was a 1/2 wave end-fed, but, I was not sure if the gamma would even be suitable for this use--and I attempted to leave my original question open-ended to catch this, if that was the case.

I am glad you pointed out the center of a driven element, such as in a yagi, is "dead" and can be attached directly to ground. If a 1/2 end-fed monopole can be matched with gamma--would that still be the same case, only here the "end" could be attached to a grounded mast?

Thank you for your reply, it is greatly appreciated.

Warmest regards,
John

However even when using the theroretical plot, the field difference between 0.25 lambda and 0.5 lambda radiators is 1.65 dB (380 vs 314).

Going from 1/4 wave to 5/8 wave the field ratio is even more: almost 3 dB (440 vs 314).

I have seen it written on this NG that an improvement of antenna gain of as little as 1dB is worthwhile.

RF

PS: I see I read the wrong side of the chart in my earlier post. Thanks for your mercy <g>. Well, the point was right, even if the numbers were wrong. /RF

What is the gain of a dipole over an imaginary isotropic antenna? I
believe I read 7.x somewhere. Whatever it was, it was greater than
anything I expected.

Thanks
Buck

Oh my. It is time for a story. My students use superb oscilloscopes that are actually computers with a D-to-A converter used to display waveforms. When measuring things such as the peak-to-peak size of a periodic waveform, students (being students) initially writedown the number exported by the oscilloscope. Whereupon, I ask the student if they wrote the computer code that exported the number and, if not, why did they believe the result. The student is sent back to note the max. and min. value, and to perform the reliable calculation of subtraction.

NEC source code exists, is understandable, and has been verified many times by independent persons. I teach my students to avoid using tools that can not be verified at a fundamental level. Of course, rules-of-thumb are an important part of error checking, and somethings are only amiable of being approximated with a heuristic equation.

I have learned many, many principles from using EZNEC which is
a really great learning tool. Look at it as reverse engineering.
You wonder why EZNEC reports such results and then you go discover
why. Modeling with ELNEC and EZNEC has taught me as much about
antennas as any other single source including Dr. Balanis' graduate
level college antenna course at ASU. One doesn't learn anything by
avoiding learning EZNEC. Dr. Balanis was amazed that an Intel
digital engineer already knew so much about antennas and I owe
that, in large part, to ELNEC and EZNEC.

In *free space* the gain of a dipole over isotropic is about 2.14 dB.
Over ground, the reflections from the ground add another few dB.
dBi is *always* referenced to free space. An isotropic over perfect
ground would probably have a gain of about 3 dBi assuming no destructive
interference. A dipole over perfect ground has a gain of about 7.5 dBi.
Rule of thumb: A dipole over average ground has a gain of about 6 dBi.

Source record: 79666

Richard Fry wrote:
"---range from about 690 mV/m for a 0.05 wavelength vertical to about 641 mV/m for a 0.625 wavelength vertical.

On page 871 of the 1955 edition of Terman`s "Electronics and Radio Engineering" is Table 23-1, "Directive Gain of Simple Antennas Relative to Isotropic Radiator".

The directive gain of an elementary doublet, assumed to be infinitesimally short, is given as 1.5. A resonant 1/2-wave wire is given a gain of 1.64 in the same table.

Terman says on page 870:
"Directive gain depends entirely on the distribution in space of radiated power."

So, the miniscule doublet puts 1.5 x as much power in its best direction as does an isotropic. This is 1.76 dBi according to Kraus.

From Terman`s dB table on page 8, a power gain of 1.5 is a little less than 2 dB gain. Kraus says 1.76 dB. A power ratio of 1.64 is more tha 2 dB, but less than 2.5 dB gain. The gain difference between a tiny dipole and a 1/2-wave dipole is almost insignificant. Certainly it is less than 1 dB.

Kraus`s 3rd edition of "Antennas" has Figure 6-2 pn page 192 which gives gains of common antennas:

An isotropic (uncommon) has a directivity of h1.00, and a gain of 0 dBi.

An elementary dipole has a directivity of 1.5, and a gain of 1.76 dBi.

a 1/2-wave dipole has a directivity of 1.64 and a gain of 2.15 dBi

A short monopole gas a directivity of 3 and a gain of 4.8 dBi.

A 1/4-wave monopole has a directivity of 3.28 and a gain of 5.2 dBi.

A 1/2-wave monopole has a directivity of 4.8 and a gain of 6,8 dBi.

With specific gain figures, we don`t need to characterize figures as large or small. I just hope I copied them correctly. Better yet, get your own copy of Kraus. It`s in print and well worth the price.

Best regards, Richard Harrison, KB5WZI

Buck--
See: http://www.maxstream.net/helpdesk/article-27
Gain of a dipole is 2.15 dB over an Isotropic - but
qualify that as in a direction perpendicular to the
direction a dipole points! a deep null in signal
occures in the directions that a dipole POINTS.
If vertical polarized , there is a deep null of the top,
and bottom of the dipole- maximum radiation around the
circumfrence , perpendicular to the dipole. (kinda like
a donut) . The only time you will see bigger numbers
is do to sales hype, or- because someone has included
ground reflections into the gain situation ! At least
a couple of antennas on E-BAY, and other places have used
this when "advertiseing" their antennas- If an antenna
pattern looks more like a punk rocker's hair-do, then the
goodyear blimp, or for a dipole/longwire, like a cigar,
the pattern shown has considerable ground reflections,
with undesireable angles of radiation. (at least that
the best way I can describe the situation, someone)
do better??). Jim NN7K

Yes, I am quite sure you are correct.

And, perhaps no one knows, or no one does it the old fashioned way and has the formulas and steps at their disposal, I may have to seek other sources than here.

However, I am a software engineer, once I understand the underlying math and methods I can write such an application myself.

When the final drafts of these programs are released, antenna design, I am sure you will just draw your antenna on virtual graph paper with ruled lines, such as many of the draw programs have. And, be able to add any inductance or capacitance just by selecting the point with the mouse, and then entering values--the application will do everything else for you, including making suggestions for improvement, matching, special conditions, etc, etc--much like CAD (Computer Assisted Drafting) applications.

However, whether I use software, or simply divide 468/Fmhz, I still get a half-wave.

It is fine if one wants to rely on software--I make my living on those who do, I LOVE those people!--I just don't wish to invoke that method, later when my understanding is absolute (well, greater than it is now) I may, or write software specific to my needs...

Warmest regards

I was trying to calculate the ERP of his HT into a vertical dipole and
accounting for the loss of RG-58A coax of 25 feet. It seemed his ERP
was outrageous compared to what I would have expected. I calculated
it with the gain of the dipole over an isotropic as referenced in the
ARRL handbook. The only figure in there was the 7.5 dBi gain.

I saw a harendous (sp) number for his ERP so I decided to stop the
explanation until I could confirm this. I figured I was doing
something wrong.

His HT is about 5 watts output.

Thanks

Isn't gain something that comes about by reshaping and polarizing that
isotropic radiation?

An isotropic antenna in free space radiates equally
in all directions, i.e. in the three physical dimensions.
The locus of points of equal field strength would describe
a sphere in three dimensions.

Thanks, Cecil -- what got me thinking about it was a friend
brought up this discussion of , say Moonbounce , with say
Lefthand circular polarization , as observed from Earth.
(which on reflection should be RIGHT HAND circular polarization
upon return to earth, if to a Linear , Flat plane, like a billboard)
and one of the experts there said to him "NOT so fast about the
signals being 100 % out of phase" (think had to do with
Faraday effect) - got me wondering about the effects -apparently
NOT a concern with dBi calculations! thanks, Jim NN7K

Hi Brett,

That question rather goes beyond the nutshell lead-in. However, for
the nutshell:
1/20th wave gamma rod;
capacitance about 5 to 8pF/Meter-of-wavelength;
gamma rod roughly half diameter as the radiator and spaced
roughly 1/100th wavelength from it.

With all the "roughlies" (a product of nutshell precision) it pays to
make the capacitor a variable, or the gamma loop length variable. All
such roughlies are also contingent upon the radiator's size WRT
wavelength.

To translate the capacitor characteristic:
for 20M band it would be 100 to 160pF

> are, as has been mentioned here many times, notorious for RF
> interference.

There are two classes of warts. A simple transformer will convert 120 VAC to
maybe 12 VAC. As long as the transformer core does not go into saturation,
then this wart produces zero EMI. OTOH, a wart that rectifies the AC to DC
has the potential to create considerable EMI. Hams should always consider
the possibility of RF pollution from anything they install in or around
their shack. Variable speed fans, adjustable lighting devices, arc-discharge

lighting, battery chargers, wireless network modems and other personal electronics all need to be evaluated for their EMI potential. As a ham, you shouldn't be surprised to find that fluorescent or HID lighting causes RF noise!!

You can partially protect your shack by always looking for an FCC or CE compliance marking. Assuming that the devices are legally marked, FCC & CE marking is a bit of evidence that the product will be limited in RF emissions. But remember, the standards are based on "average consumer" conditions, NOT on a special consumer sticking the product in proximity to a sensitive receiver. As a ham, you place yourself in the position of an "expert user" of consumer electronic devices; you are no longer a clueless appliance buyer, but someone who understands RF energy and the vagaries of its creation and propagation.

You can either accept the responsibility to control EMI in your hobby, or go back to 11 meters and cable TV.

Jerry, WA6E wrote:
"Just take two resonant antennas on whatever frequency you want, aim one towards the repeater and the other towards your house.

Connect them with good coax as short as possible but the length must be a multiple of 1/4 wave at the desired frequency."

Yes./ Maybe an even-multiple of 1/4wave. Odd-multiples may be particularly bad.

Suppose the two antennas are identical, mounted high and in the clear. The radiation resistance of one antenna matches the other, so we have a matched source and load in both directions. Maximum power can be intercepted and re-radiated.

A 1/4-wavelength transmission line inverts the impedance presented. A too low impedance at one end becomes a too high impedace at the opposite end and vice versa.

A 1/2-wave length of transmission line reoeats the impedance presented to it at its opposite end, no matter what the Zo of the line is. If the terminations are matched, a repetition through the line is exactly what you want.

Best regards, Richard Harrison, KB5WZI

Antenna performance figures are affected by many variables, so performance claims can be very misleading. To try to keep everybody on the same "level field", the proper way to define performance is to relate gain to an isotropic reference in free-space conditions. This is nice physics, but certainly not real life. Extremely few people can place their 20-meter dipole in free-space. Most humans string their dipole from tree to tree, or buy as much metal tower as possible. Those trees, other buildings, tower metal, guy wires, coax cables, other antennas and the proximity of the ground all modify the antenna performance in difficult to predict ways. Some might argue that free-space conditions can never exist in real life, so antenna testing in their back yard is better than free-space projections. This would be true, if everybody's back yard was electrically identical to yours. Thus, until everybody has a standardized back yard, free-space, isotropically referenced data is your best guide.

Oh yes, laws are made to in most cases protect the greater part of the
public and we all have to abide by the laws. I have no respect for any
person regardless of what trade they perform, if they break the law then
they are a criminal. If it be the FCC, Industry Canada (Canadian FCC) or the
traffic laws then they deserve to be caught and punished. Like you say, if
it be a cop, doctor, trucker or lawyer, we all have to abide by the law
others wise it will be a complete mayham free for all.
I dispise truckers who are of the oppinion that they are above the law, I
know of a fair number of truckers who wrote and passed the exam for their
ham tickett and now only use their CB for loading docks and traffic reports.
But most of these men and women have higher education levels than the old
truckers use to.
Any trucker who thinks he/she is above the law is only fooling themselves,
because it's only a matter of time before they will get caught and they will
eventually. I've been at a scale when the safety bliz happens all across

Canada/USA and the authorities will go right through a tractor and want to see every licence for every radio in the truck. And if the driver doesn't have one he losses the radio. And I'm glad they do this, cause it cleans up the amateur bands from these pirate amateurs. I get really ticked when I hear some fool talking on a radio who thinks he's some sort of a "god" because of his trade. Let's face it the astronauts had to pass the exams to get their amateur licence(s) so why should anyone else get it given to them. I wish the FCC and Industry Canada had more powers to eliminate the interferance from unlicenced, licenced and industrial sources. The laws are there but these agencies don't seem to have the muscle to enforce them, wheather it be from monatary cut back or whatever. I remember the days when an unlicenced operator was more likely to get caught than not and this was a big deteriant in controlling the problem. Now days it seems that we as licenced operators have do these different agencies job for them. I guess that's another topic for another time.

Re-shaping, yes. Polarization, no. Gain is defined by power radiated through a unit area, or power density. It doesn't matter which way the E-field vector is pointing at any given instant.

A good physical analogy is to think of a circular baloon. If you squeeze the baloon, it will distort from circular. The narrower parts will be "nulls", and the bulges will be directed energy, or "gain". The tough part of antenna design is getting those bulges to point where you want them. For instance, if you want GPS reception, you want good performance roughly from horizon to horizon, and no nulls overhead. But if you want to talk with other hams on a hike, very few of them will be located 15,000 feet overhead, so you can optimize your antenna to not waste power vertically. Indeed, the best pattern for this work is a squashed-down to the horizon, equi-azimuth pattern.

Ya know Ed I have never met you so I can't say for sure if you are a pontificating idiot or not. I have never been on CB and the cable TV is mostly the History Channel and such. A "teaching post" , albeit boring, would be acceptable but the above zinger is not funny nor complimentary of the guys on this thread. My installing of the halogens were from the point of my back 9 of life eyesight when connecting things in back of the equipment not to be on when I was working quasi land with 5 watts. The condescending attitude displayed in your pontification is like many hams I have run across in the last 40 years of this endeavor and causes our service to loose valuable young people. Unfortunately I am not young but on the other hand I have been around enough to recognize those who would lord over others from a "technical" standpoint. Yep there Ed I have used bypass caps, torroids, made brute force filters etc. to make my operating a bit more enjoyable ...now if they only had a filter for your type of letter and attitude we all would be ahead.

Your not alone on this one, I've been pulling a set of turnpikes (two 53 foot trialers) and had this pulled on me as well. Like "cl" said there are rotten apples in every trade.
Over the years of driving in every state and province in North America (I've seen bad drivers in every one too) I've even had an ambulance (no lights/siren) cut in front of me while I was driving the speed limit of 55 for trucks and given the finger to boot. Even got told by a state trooper in NY that I was in his way and pull off the road where there was not shoulder. It seems that intellegence wasn't a requirement when they gave this individual a badge,pistol and drivers licence. On the hand I've seen some very stupid tricks done by trucking companies and drivers. One company in paticular had a habit of sending new green drivers out west into the mountains and in most cases it was a really bad decission for both driver and company. When you have to talk a pretrified driver down a mountain road so he won't kill himself and a lot of other people I really think something is wrong here. For the last few years I drove before retiring I drove the I-5 corridor, Vancouver Canada to LA and back once a week. And so many times I would see inexperienced drivers trying to come down Mount Ashland and the Grapevine in Ca. and their brakes would be smoking like a forest fire. By the time they reached the bottom they wouldn't have any brakes left on the truck or trailer. Driving a car on snow and ice is scarey, you should see what it's like driving an 80,000 lb. truck and hopfully the truck in front and behind you has an experienced driver in it. Now you know why most of us old truckers go prematurely gray and retire long before we are 65.
I too drive two wheels and I hate it when I see a fool riding more bike than they can handle and it's the same with four or eighteen wheels.

For what it's worth, I'm going to mention this, as it follows along with the thread and ultimate mention of "ambulances" being rude. Yes, the drivers of them can be rude. Give em an emergency vehicle, and all common sense goes out the window. I am involved in Fire and was at one time - EMS. Here, blue lights are used to get firefighters/emts to a station or call. Some take them for granted as a ticket to speed. They are not. They are courtesy lights only. No one is required to pull off for said vehicle with a blue light. The lights "must" be listed with the local State Police Barracks. Our station doesn't have a problem with lights as most live close enough to not need them. But there are others who go whizzing by to "their" stations who

"have" abused them. They were caught and fined too. The State Police here have been known to pull over anyone using a blue light and even Ambulances going over the speed limit - to question the legitimacy of a call and thus the speed being used. Some folks who had to travel through our town to go to "their" station (not ours) were getting pretty bad with abuse of lights and speed. I don't care WHO you are or THINK you are, no one has the right to defy the law. They're made for a reason. As was said by me and alluded to by another gentleman, toss the laws out the window, and it will be complete turmoil. The wild west will look like a kiddie carnival compared to what we would see. Everyone must play a part to keep what we call peace and civilization - at a pace for all to survive.

Tom:

You can tell if I'm "pontificating" by reading my text and determining the validity of my advice. OTOH, I am getting weary of people who choose a hobby that involves RF propagation, and then get all whiney when they add an obviously noisy RF source to their environment. If you want to be a ham, then I'm going to hold you to a higher standard. And what should be an example of not meeting that standard?

As for "losing valuable young people"; well, if some guy tells me his arc-welding hobby interferes with his DX contesting, well, that's just too pathetic for futher comment.

As a self-declared "old guy", I would expect you to understand the concept of minimum standrds of performance. Remember when FCC exams really meant something? You sound all "new-age touchy-feely", finding personal insult in a general comment about performance standards. Now I'm truly sorry that you interpreted my post that way, and it's too bad you couldn't say something about the technical content. I will apologize to any technically apt CB'ers and TV viewers who also may share your sadness, but reasons of visual ability, dexterity and age don't excuse lack of basic RF understanding.

BTW, there IS a filter for my type of post. (True, the best filter would be your ability to understand a post.) You can simply ignore my postings, as I always post from the same account and I clearly identify myself. You could also set up an automated filter process, but then that would require technical competence in software operation, and that brings up a whole new area in which you may find offense. Best we not go there.

John Smith wrote:
"In other words, what set of formulas would give you length, conductor spacing, gamma capacitor value----?"

It looks experimental to me.

My ARRL Handbook says that the T match has an advantage in that a pair of transmission line attachment points equidistant from the center of a resonant wire has a resistance between them. Therefore it is possible to choose points which match the line Zo. Problem is the physical distance between the attachment points probably does not match the line spacing. The handbook suggests a T match made like a folded dipole with single-wire extensions at its ends. This looks as if it would require experimentation.. It seems suited for parallel-wire lines.

The gamma match seems to be similar but an ubbalanced scheme where the grounded line conductor is attached to the center of the radiator and the ungrounded conductor is connected to the wire at a distance from the center of the radiator which results in a low SWR on the transmission line. A variation treats the gamma match as if it were a shunt tower feed arangement.

The gamma match becomes a feed loop containing a ground path. The feed loop is sized to that required for a resistive component which matches the Zo of the transmission line. The loop inductively couples the antenna with the transmission line. The loop`s reactance is always inductive and can be tuned out with a series connected variable capacitor.

It seems a good cut-and-try project to me. Maybe perfect for Art Unwin.

Best regards, Richard Harrison, KB5WZI

Dear John Smith (no call, no location)

Your questions contain assumptions. You assume that formulas amiable of
being programmed into a TI calculator exist for what it is you wish to do.
I doubt that they exist.

To borrow a term from your job, top-down is needed. Start with the
ARRL's Antenna Book. When you have digested its teachings, read either
Kraus' 3rd edition or Balanis' 2nd edition. Start at the beginning and
follow the road. It will be an interesting journey.
Regards, Mac N8TT

Source record: 79691

ok...
I cut a 1/2 wave monopole for 28.4Mhz and used the dimensions according to what you stated. The capacitor is homebrew from 3/16 acrylic sheet with aluminum plates, configured as a compression variable, true pf is unknown (with spacing and dielectric of acrylic and size of plates, should max at ~150 pf) --but plenty of adjustment, both sides of "null" on swr meter.

However, the shorting bar on the gamma rod had to be raised to ~3 ft. (adjustment above or below this height only increases swr), here the swr is ~1.7:1. I cannot find a configuration on the gamma which brings the swr under that figure... lengthing/shorting monopole +2 to -2 inches has negligible effect and not for the better.

Lenght of coax from rf source to ant seems critical, when coax is shortened or lengthened, gamma must be adjusted (but is always around 3 ft)

The gamma rod length seems to be quite above what the figures you gave me would suggest (from what you suggested, 1/20 wave (~20 inches or do I have that correct?)--what am I too blind to see to see here, or what I am I ignorant of?

Your continued help and advice would be most appreciated...

Warmest regards,
John

As Richard H. said, find the point where the feedpoint
resistance is 50 + jXL ohms. That must occur somewhere.
Then tune out the reactance with a series capacitor.

Hi Brett,

This is a classic symptom of feedline interaction with the feedpoint Impedance. Basically, the exterior of the cable is acting as an uncontrolled tuning element that is bridging your attempt to tune the antenna. To correct this one indication, you need to choke the feedline. This is accomplished by one of several methods.

We frequently recommend what is called a "Current BalUn" which is a series of ferrite beads strung onto the coax near the feed point. Another method is to simply coil the coax with half a dozen turns of about 6 inches diameter. Either method will decouple the feedline from the feedpoint. There's more to be said, but that can be discussed at another time, or you can research that in the archives using the keywords in quotes above. This is successful with Low-Z loads because the choke is Hi-Z in comparison - your drive point choice presents a problem in that regard.

That problem is that a halfwave is extremely sensitive to environment, especially in the face of unchoked lines. This is a fact of life in that for a Hi-Z load, nearly everything nearby looks like a short circuit unless you can hoist the antenna out of the way. The choking action will have to be extremely good to overcome this (or you will have to insure that the external coax length is also halfwave in length - this is one of those CB antenna/coax issues that rarely gets discussed and becomes lore instead of learning). Hi-Z loads are usually matched with Hi-Z circuits through voltage matching, the Gamma match is more a Low-Z device working as a current transformer. Its standard application, nearer the middle of the halfwave antenna, would be more suitable.

To achieve this, isolate the bottom end of the halfwave (mount it on an insulator, the details which follow will be challenging). Make sure you can snake the coax up inside the antenna (this presumes it is tubular of sufficient diameter to pass cable up inside). Break out the cable halfway up (care must be given that this does not substantially weaken the whole of the antenna). Build the gamma match (external of course) here and drive it against the radiator body with one lead of the coax going to the gamma structure, the other side going to the break out hole.

All in all, a SWR of 1.7 is not shabby for a first pass approximation for a physical solution. If you decide to stick with your current implementation, you might try making the gamma tube larger than the diameter of the radiator (capacitance stays the same). We are departing from the regime of nutshell math.

By this (classical design), the work revealed in full sized, folded dipoles (and monopoles) teaches that the size ratio of the two elements (in this case approximated by the radiator and the gamma element), and their proximity, yield a step-up or step-down relationship in drive point Z (depending on which, larger or smaller, is being driven). This is like conventional transformer winding ratios, except in RF it is embodied in diameters and separation with complex results (not as simple as counting turns and being done with it). This is further complicated by the structure not being a classic folded design - I am merely extending the metaphor, returning this to nutshell theory.

This means it is up to you to close the gap through experimentation, observation, and correlation. There may be a limit in what you can achieve, but you seem close enough to vary a few parameters to see if there is any progress.

Hi All,

For others following my strained metaphors, consult Johnson and
Jasik's "Antenna Engineering Handbook," "Impedance Transformation as a
Function of the Ratio of Conductor Sizes" (pg. 4-17 of the second
edition).

This topic has always been confined to full sized folded quarterwave
monopoles or halfwave dipoles and I have not observed any equal (that
is, comprehensive) treatment given in terms of T or Gamma matches. Of
course, there may be every reason why such has never been done.

Tom

Although I can see your point about Ed's sharp tongue, he is likely a
techincally bright guy who is as intolerant of old guys like you and me who
make more mistakes than we'd like.
I'm 74 and used to be a fairly active antenna making ham in the 1960s.
But, I dont know crap compared to the guys who currently study about
antennas and electronics. I'd bet that you and I will have more comfort if
we dont get overly excited when we get yelled at for writing things that
dont quite fit with the current level of 'technical knowledge'.

There is so much really good technical guidance available within this news group that it doesnt make any sense for us old guys to get upset when we get insulted. I've found it alot easir to read around most criticism. That way I can continue to enjoy this nifty way of keeping aware of antenna development (without having to go back to books and class rooms).
You are welcome to tell me to F888 off if this post offends. I only offer it as a way of showing that even though I see your point, I also consider it so unimportant that you and I get yelled at occasionally.

Jerry

Yes, I understand about the transformer action of differing conductor sizes
at rf freqs.
I interned for a tranformer manufacturer many moons ago.
I will experment with differing diameters of the gamma rod. That is one new
variable I can introduce....

Richard:

Thanks, I think you have at least one problem I created in check. I forgot
to place ferrite beads over the coax, at the antenna, I guess I was thinking
the gamma was some sort of increased isolation. It is now so apparent--now
that you mentioned it...

--
have said of Jesus Christ.

598. It is not by that which is obscure in Mahomet, and which may be interpreted in a mysterious sense, that I would have him judged, but by what is clear, as his paradise and the rest. In that he is ridiculous. And since what is clear is ridiculous, it is not right to take his obscurities for mysteries.

It is not the same with the Scripture. I agree that there are in it obscurities as strange as those of Mahomet; but there are admirably clear passages, and the prophecies are manifestly fulfilled. The cases are, therefore, not on a par. We must not confound and put on one level things which only resemble each other in their obscurity, and not in the clearness, which requires us to reverence the obscurities.

599. The difference between Jesus Christ and Mahomet.--Mahomet was not foretold; Jesus Christ was foretold.

Mahomet slew; Jesus Christ caused His own to be slain.

Mahomet forbade reading; the Apostles ordered reading.

In fact, the two are so opposed

If the formulas, charts, etc. don't exist, then I am extremely lucky. Most
of the time (OK! Maybe ALL the time) my efforts just end up duplicating what
past expermenters have already done. I make notes as I go, if I don't find
what I am doing in some other obscure work--or as knowledge another has, I
will be tempted to place it in a form where others might use it.
What I mean is, I will not be disappointed--and very happy if what you
suspect is true.
"Top Down" (hey, is that guy in a convertible?) is great, however, bottom up
has its uses too... OOP(s) (a pun--Object Orientated Programing--for
non-coders), I hope some of my old professors aren't around here! (Darn!
that Richard, now he has me doing it) <grin>

Richard H.:

I had only used a "universal stub" and "L-Network" to match a 1/2 wave end fed before now. The gamma seems interesting.
Just for my curriosity, I will do a full-wave with a T-Match in the next few days (seems a 1 wave vertical is best suited for high angle radiation pattern.) I will keep your analysis in mind, especially at that time--thanks!

Things are getting too fuzzy here, so I'll try to sharpen the focus a bit.

First, you self-declared "old guys" have only about a decade and a half seniority on me. I have always tried to respect ability, regardless of the age of its holder. OTOH, old jerks are still jerks.

Second, I have met myself, and I can assure you that I can be considered an idiot (having already progressed through the grades of imbecile and moron) . But I try mightily to never pontificate.

Third. silver-tongued, omniscient orators sometimes close with a zinger that's a bit too barbed, so I again apologize if my karma ran over your dogma.

This is all true, of course, but might lead some to the invalid conclusion that it also applies to monopoles (whips) of 1/2 wavelength or less working against a ground plane, such as in mobile operations or back yard verticals.

When a vertical radiator works against a perfect ground plane, the electrical length of that radiator effectively is doubled. So in reality an electrical "1/4-wave vertical" has twice the gain of a *1/2-wave* dipole because of the image effect of the ground plane, and the fact that all radiation is confined to one hemisphere (above ground). Note in your quote from Kraus, p 192 that the short monopole and the 1/4-wave monopole each have 3dB more gain, respectively, than the free space elementary (short) dipole and the 1/2-wave dipole he also lists there.

Using your statements above the line, one might think that it rather pointless to use anything longer than a 1/4-wave vertical. But going from a 1/4-wave to a 1/2-wave vertical in fact will add ~1.6dB of gain at the peak of the pattern envelope, and a 5/8-wave vertical will add almost 3dB. These are worthwhile improvements in system performance. Broadcast engineering consultants have recognized this, and used it to advantage for decades.

> Better yet, get your own copy of Kraus. It`s in print and
> well worth the price.

Good advice (I already have it).

An *end-fed* one wavelength vertical fed against ground has
a high angle radiation pattern, e.g. 36 deg TOA. A one wavelength
vertical with a T-Match is a center-fed antenna. Such an antenna
has a *low angle* radiation pattern, e.g. 11 deg TOA.

John, do not allow yourself be led astray by the waffle on this newsgroup of the importance of supposed antenna gains and the differences between one exaggerated radiation pattern and another.

Real professsional radio engineers (who are extremely few and far between) who, to make an honest living, are obliged to work in the real world, and are accustomed to dealing with radio-path propagation uncertaintainties of plus or minus 10, 15 or even 20 dB.

But perhaps you already find enough amusement with such silly back-to-front ratios as 50 dB and this little warning is unnecessary. I'm sure it is.

Reg:

Your point is well taken here. I was wondering if it was just me and, I ended up throwing away valuable posts because I was unable to recognize pertinent posts; some posts do leave me asking a question, "Why would some authors even post replies which contain no useable facts, data, and comments--what is their intent?"

In the end, I chalked it up to, perhaps, younger people entering the arena of discussion in "the real world" and, perhaps it would take them a bit of time to experience what works and what does not.

Whatever this phenomenon is, your comments have been reassuring to my not being alone in observing this behavior, THANKS!

Warmest regards,

John

>"end" could be attached to a grounded mast?

The gamma is normally used to feed the center of the driven element of
a Yagi where the feedpoint impedance is lower than that of the
transmission line and it is desired to have an unbroken element.

Another application is to shunt feed a grounded monopole, such as when
a grounded tower is used as a radiator. In this case too, the base
impedance is lower than the transmission line Z.

Both cases use the gamma as an impedance "step-up" transformer.

Because you suggest an end-fed half-wave, where the impedance is much
greater than 50-70 Ohm, I see no compelling reason to opt for a gamma
feed, other than the case when you want to ground the end of the
radiator (which may be what you have in mind).

While it is convenient to think of the gamma as a system where a "50
Ohm point" is located on the radiator and a tap made to it, the
reality is that the system is *much* more complicated and involves
mutual coupling, transmission line effects, etc, between the gamma rod
and the radiator. A moments reflection (no pun intended) will make
this obvious. If a "50 Ohm point" is the only goal then the gamma rod
diameter and spacing would not be factors.

Additionally, there is a multiplicity of combinations that will
present a match, at one frequency. Each will have a different
effective bandwidth, however.

Before I'm taken to task, let me add, "is usually lower" than the
transmission line Z.\

Shunt feeding can be/is done on towers longer than 1/4 wavelength
where the Z at the bottom of the tower is higher than Zo.

200. Re: Gain over an Isotropic

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-04 17:40:09 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <11532gd6fk49nbf@corp.supernews.com>
Source record: 79719

Imagine that you put 100 watts into an isotropic radiator in free space and measure its field strength at some distance. Then you create a ground plane like the ones used by most modeling programs, perfectly flat and infinite in extent, and make it perfectly conductive. Now distribute that 100 watts evenly in all directions, above the ground plane -- imagine a sort of hemi-isotropic radiator which does this. Measure the field strength at the same distance from the radiator as before. You'll find that the field strength is 3 dB higher, and the power density twice as great, as for the isotropic source in free space. It's simply because you're distributing the same amount of power in half the amount of space.

That illustrates the first principle, that putting an antenna over ground gives you an automatic 3 dB increase in average field strength compared to free space. If you compare the field strength of an antenna over ground with a free space isotropic source (i.e., give its gain in dBi), you'll find it has a gain of 3 dBi when averaged in all directions. (EZNEC's "Average Gain" calculation automatically takes this into account and normalizes to 0 dB when a ground is present; NEC-2's average gain calculation doesn't.)

You can also pick up about 3 dB additional gain because of the increased directivity you get when putting an antenna over ground. You get the same pattern you'd have if there were another antenna below the ground (an "image" antenna) and with out of phase current relative to the actual antenna -- it's like having a two antenna beam. (Pattern gain won't usually be exactly 3 dB because of the impedance change of the antenna caused by interaction with the ground -- when the ground is perfect, it's exactly the same as mutual coupling to the "image" antenna.) So typically a dipole over ground has a gain somewhere between about 3 and 6 dBi -- around 4 or 5 is common for most typical grounds and heights.

Comparing the gain of an antenna to that of a dipole over ground requires calculating or measuring the gain of the dipole over ground -- you can't just assume some gain. The most universally used way is to get both gains in dBi, since dBi is universally defined and understood, then subtract to find the difference.

Roy Lewallen, W7EL

J:

College was and is a great institution.
However, the most valuable professors/instructors I ever had the pleasure to study under seemed to share one common element--they had all first worked in private enterprise before entering the academic professions (scouting rounds a guy out!)
My first degree was in electronic engineering. When the focus of this seemed to move off shore and other employment opportunities became available (and the Apple, then the IBM PC, came to be), I returned to college and focused my attention in the field of computer science.
Being an older student at that time and possessing a bit of "street-smarts", I was able to side step issues which I had found NOT be in "vogue" of my instructors beliefs.
Although these institutions are a great forum for debate and argument--I was able to see little value in endangering my grades with such which would be contrary to my instructors favorite pet ideas (indeed, while in their classrooms, they all thought--I thought, they were the most handsome (or beautiful--if female) and gifted instructor(s) I ever had the pleasure to study under <grin>.)
Some instructors are quick to point out, "There are NO dumb questions, just dumb people who don't ask questions."
However, although they may state the above--following their own advice seemed to be a bit more of a challenge to many of them and, some were better in the implementation of that ideal than others; somehow, it left me with the opinion that a more accurate translation to this advice would have been, "If you don't agree with me and the course material I have chosen for this course--YOU WILL PAY!"
But, I make no mistake--I am humbly indebted to ALL instructors for their time and efforts--I value all who lives I touched in those hallowed halls.
To this day, I do work with encryption/decryption methods and protocols. Frequently I employ another questionable practice--security through obscurity; this fills my dreams with seemingly psychic visions of past instructors cringing in dark corners in loathing contempt and fear of such arcane and cheap methods...

Rather frequently I utter (under my breath), "Whatever works!" <guilty smile>

Warmest regards,
John

It's important to realize that the graphs you posted are for surface wave field strengths. This is equivalent to far field strengths at zero elevation angle over perfect ground.

Amateurs seldom communicate by surface wave, except for local contacts. When the vertical is surrounded by real ground, attenuation of the sky wave at lower angles occurs. One of the results of this is that the antennas which concentrate energy more at lower angles end up losing a greater fraction of the total radiated energy. This tends to decrease the gain difference between a 5/8 and 1/4 wave vertical, for example, over a typical sky wave path.

In the case of VHF/UHF mobile operations, which are essentially line of sight, the finite size of most ground planes (e.g. a car top) can affect the pattern considerably, again altering the gain difference between various heights of verticals.

While there's an extensive body of well established and proven knowledge in the broadcast industry, we have to be careful in applying it to typical amteur communications. Often, the conditions are different (as in this discussion, of surface vs sky wave propagation; or fixed vs variable frequency operation), and the important criteria are different (a few percent difference in coverage area is important to a broadcaster because of its impact on advertising revenue, but a fraction of a dB is seldom important to an amateur; a broadcast phased array can take a long time to design and adjust, but amateurs want to switch or change directions). So we can't just assume that an antenna or method that's best for a broadcaster is best for us.

Wes:
I believe you are correct--my use of the gamma is rather unconventional here (how would one describe this antenna, "A J-Pole without 1/4 wave matching section?", having been replaced with the gamma.)
However, my first impressions from my limitied observations is that there IS an increase in received signal strength from the most distant stations, and appearing as 1-2 S-units with the use of a gamma match (ok, maybe something else is responsible--but I can't see it.)
The gamma I am using is constructed of all copper (3/8 tubing at the moment) with soldered connections, other than the sliding clamp attaching it to the end fed monopole (copper clamp to the copper element of the monopole)--it replaces an L-Network of #8 copper wire using a capacitor of copper plates and telflon dielectric material.
Unless there is another varible at work--the gamma side of the monopole seems to have a bit more of the patterns favor--but barely noticeable (spacing of the gamma rod from monopole is ~4 inches.)

(Sigh!)

I put all the gamma match info I have on a.b.s.e (I think; it hasn't appeared there yet)under subject "Gamma match article and executable." One is an article in PDF format and the other is a DOS executable for designing. Use whichever one floats your boat.

Reg, is this the question? Where is the ratio of the real
part of the net voltage to the real part of the net current
equal to 50 ohms? Or is it more complicated than that?

Just to take a side avenue to this all, I dropped down another 1/2 wave element adjacent to 1/2 monopole under discussion, with a shorting strap the top of the elements (converting the 1/2 monopole into an upside down "U"--or, resembling a slim-jim with 1/4 wave match replaced by the gamma), guess what? Yes, a noticible improvement....

Hi all......
I have a ground mounted 40 ft vertical wth an extensive buried radial system that I have been using with good success on 40 thru 10 meters and have been feeding it with 50 ohm coax to a 4 to 1 voltage balun at the base of the antenna.
I recently tried feeding the antenna with 450 ohm twin lead and a Johnson Matchbox with the twin lead parallel to the ground at about 6 inches elevation.
I am pretty gratified to find the Matchbox will do a fine job of balancing and matching on 80 thru 10 meters.

Anyone else try this?

I haven't tried feeding an unbalanced antenna with balanced line before, unless there is a balun at the feedpoint of the antenna...have always thought balanced line will only feed a balanced antenna....the exception being an end fed zepp, or a 30 ft vertical with one 30 ft counterpose.

The way it looks to me, the speed of propagation is pretty much the
inverse of the squareroot of the product of mu and epsilon for the
dielectric between conductors.

That's almost correct, but not quite. You need to modify it by changing "the dielectric between conductors" to "the medium containing the fields". Inside a coaxial cable, both are the same, so you can easily calculate the velocity factor from the dielectric constant (relative epsilon) of the dielectric. In the case of ladder line, TV twinlead, or microstrip line, though, part of the field is in the dielectric and part is in the air. So the velocity factor is a function of the dielectric constants of both. Often, an "effective" dielectric constant is calculated that fits the rule you mentioned(*). For the types of line I mentioned, it's between those of air and the dielectric material. It's not at all trivial to calculate, so it's usually determined by measurement or a field-solving computer program.

In the case of an insulated antenna wire or one with a ferrite core on the outside, the "other conductor" is usually a very great distance away so the vast majority of the field is in the air. Also, the simple formula you refer to might not apply when the distance between conductors is a substantial fraction of a wavelength or more. If you take a piece of coax with solid polyethylene dielectric and measure its velocity factor, you'll find it to be around 0.66 (following the formula you mention). But if you strip off the shield and use the same center wire and insulation for an antenna, you'll find the insulation slows the wave on the antenna by only a few percent (almost certainly less than five).

(*) In the case of microstrip line, the field distribution changes with frequency. This results in an effective dielectric constant, and hence velocity factor, which changes with frequency. With something like Teflon dielectric, which has a relatively low dielectric constant, this change isn't much. But it sure gave me grief when designing time-domain circuitry using microstrip lines on an alumina substrate (dielectric constant ~ 10), where the change was much greater.

I investigated your concept statements using NEC-2 models of 1/4-wave and 5/8-wave verticals in the 40m band (7.3MHz), working against the same infinite ground plane of "Average" parameters.

* The 5/8-wave vertical has a peak gain of 0.2dBi, 16 degrees above the horizon.

* The 1/4-wave vertical has a peak gain of -6.4dBi, 26 degrees above the horizon, and its entire radiation envelope is always within that of the 5/8-wave.

I don't know which range of elevation angles is considered most useful for skywave paths on 40m, but it would appear that with equal tx power, a 5/8-wave vertical always will have a usefully better skywave than a 1/4-wave vertical over a typical ground plane -- and probably by more than 3dB.

If you could check my conclusions on this I'd be grateful.

A typical dipole is easily greater than 90% efficient. And a double
bazooka will be considerably less efficient than a dipole.

Ask your friend where he got those figures. I'd be interested in knowing.

Hi Ken,
Those who tout the double bazooka have been misled for eons. That antenna is simply a resistance-loaded dipole and the increase in BW is due to the resistance loading of the dielectric in the coax that forms the dipole. The shunt reactance of the shorted quarter-wave sections forming the dipole does nothing to increase the BW. The principle is ok, and was used on military equipment during WW2, but for the shunt reactance to provide the increase in BW the feedline Zo needs to be at least two times the resistive component in the dipole input impedance for the concept to work. Consquently, the double bazooka as misused by the amateur community has been misengineered.

I published a long and detailed expose of this antenna in Ham Radio, August 1976, with a shortened version in QST, Sept 1976. I explain mathematically why it doesn't work as many claim. It appears as Chapter 18 in Reflections 1 and 2, and is available for downloading from my web page at www.w2du.com. Please review this document before wasting your time and energy on a dud.

From: Roy Lewallen <w7el@eznec.com>
Message-ID: <1153gtot88tsr90@corp.supernews.com>
Source record: 79592

It sounds like you might have made the mistake of connecting a wire directly to Sommerfeld or reflection coefficient ground. Doing this with NEC-2 (or EZNEC) produces a resistance of unpredictable and meaningless value at the connection point, lowering the indicated field strength by an unpredictable amount. (EZNEC gives you a warning message when you try to do this.)

EZNEC provides an option not available in NEC-2, a "MININEC-type" ground. This functions as a perfect ground when calculating impedances and currents, but uses the user-specified ground constants (conductivity and dielectric constant) when calculating the pattern. It simulates an antenna with a lossless ground system, allowing you to separately see the effect of ground conductivity on the pattern without the magnitude of the field being affected by changes in the ground system loss. The best you can do with either EZNEC or NEC-2 if you want to include ground system loss is to include radial wires just above the ground in the model and connect the vertical to them. Then, however, any differences you see will hold only for that particular ground system -- and, the above-ground approximation isn't a terrifically accurate representation of a buried system.

Using the MININEC-type ground with EZNEC (and only 10 segments, so this can easily be done with the demo program) and starting with the Vert1.ez example file, the gain of a resonant (~0.24 wavelength) high vertical at 7 MHz with "average" ground is -0.0 dBi at an elevation angle of 26 degrees. Changing the height to 0.625 wavelengths (easily done by first changing Units to Wavelengths) produces a maximum gain of 1.19 dBi at 15 degrees elevation angle. The 1/4 wave trace protrudes outside the 5/8 wave trace only from about 25 to 41 degree elevation.

But more interesting is the gain difference at various low elevation angles. The comparison is easily done with EZNEC v. 4.0 by saving the trace from one antenna, then superimposing that pattern on the pattern of the second antenna. By clicking the name of the superimposed pattern in the 2D plot window, a new entry appears in the data box showing the difference between the two at the angle of the cursor.

It turns out that the 5/8 wave really shines at really low angles when the ground is poor, but isn't so impressive when the ground is very good -- at least at 7 MHz. Over average ground, the gain difference is at or just above 3 dB up to about 10 degrees. (My explanation of the reason for the difference over real ground was overly simplistic. I apologize.) Above 10 degrees, the difference decreases. Over poor ground, the gain difference is about 4.5 dB up to 5 degrees, and over 4 at 10. So if you have poor ground, you can really benefit from a higher radiator. Over

very good ground, though, the difference is about 2 dB up to 5 degrees elevation, only 1.2 at 10 degrees, and less than a dB at 12 degrees and above. So it might or might not be worthwhile to extend the height of a tower for that amount of benefit.

Those figures depend on frequency, too, and the pattern shape varies considerably with frequency and ground characteristics. So modeling the particular situation would be a good idea before doing any expensive and extensive tower lengthening. In all the cases I looked at, however, the 5/8 wave vertical did show some gain over a quarter wave vertical up to at least 14 degrees. Whether the difference is worth the added height is up to the individual.

The efficiency graphs in The ARRL Antenna Book indicate
that the double bazooka is NEVER more efficient than a
dipole and that it has lower efficiency at every frequency
other than resonance. Is your friend an Old Wife?

I suspect your friend got his figures reversed.
Any properly-constructed half-wave dipole is well
over 90% efficient. The double bazooka gets its
meager bandwidth improvement by adding loss.

Dear Denton,

This is not to say that it will not be a problem in some way. You get
away with it primarily because the tuner end of the balanced line is
connecting only to the link - therefore floating (except for some
capacitive coupling from the link to the tank circuit).

To a large degree, the fact that the ground plane antenna is very much
unbalance, the twinlead doesn't have any way of knowing this and
doesn't care.

O.K. Reg
I'll take you up on the 50 db F/B.
There are old wives tales and then there are old wives
who just tell tales about other old wives.Which is it?
I have never read anything definitive about max F/B figures attainable.
I have heard unsubstantiated stories about narrow voids filling up between
lobes
but no data to back it up so I would call that an old wives tale.
There are computor programs that show large F/B figures, shall we throw
those away together with your programs as computor programs are all suspect?
Actually I have not seen any measured data regarding F/B radiation with
respect to
lobe angles possibly because of difficulties with respect to measuring And
also
what height the antenna must be before lobe shapes stablises.?
Now you have come forward and stated, presumably by experience,
mathematics or what ever, that 50 db F/B is silly. Why so?
What F/B figure is not silly and why, plus what are the parameters
involved that make this F/B not silly? Does this F/B relate to all antennas,
yagi's, dish forms, verticals, wire arrangements or what?
I am so pleased somebody has all this data so as to really substantiate,
without doubt, that it really IS an old wives tale ,or is it somebody just
exercising
their right to free speech regardless of content.
I await your reply with interest, and ofcourse, the scientific data that
substantiate
what IS an old wives tale and what IS not, and........ without "waffle"

Yes, air is obviously also a dielectric.

Exactly. That's why I chose to adhere as strictly as possible to
absolute generalities. ;-)

I think in the case where the distance between conductors is much larger
than the diameter of the conductor, a better form would probably be one
over the squareroot of the product of inductance per unit length and
capacitance per unit length.

.
I've used twin lead to feed a vertical, but I used a balun on each end of
the twin lead to convert it to 50-ish ohms or so for both ends. It saved a
ton of money because it was a long run.

Thanks Bob, Roy, Walter, Richard & Cecil!

Wow - all the guru's agree for once? That fact alone
leaves me to forget the idea of replacing my ladder
line/coax fed 40m dipole with a Bazooka.

Info - my current antenna started out as a Van Gordon
"All Bander", a 134' dipole fed with 100' of ladder line.
I trimmed 50' off the ladder line and have a 12' rg58
coax feeding a CD size 13 turn coax coil which feeds
the ladder line going up to the antenna (which I trimmed
to 7.185 mhz). It's a flat dipole (almost) up 25'.

Due to a lack of space, I would have had to take that
antenna down to put up the Bazooka so comparing the
two would have been almost impossible.

Thanks again, guys - you rock!

231. Re: VF, low-loss line, high-impedence line - relationship

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-05 00:35:37 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <1153qrebosdou47@corp.supernews.com>
Source record: 79598

The loss has nothing to do with the speed of travel, except that the effective dielectric constant has a direct effect on speed and an indirect effect on loss.

At frequencies from at least HF well into the UHF range or higher, the loss in transmission lines having decent insulation (e.g., PE or PTFE) is almost all due to conductor loss rather than dielectric loss. Higher impedance line has lower loss simply because for a given amount of power being conveyed, the current is lower. Therefore, the conductor I^2 * R loss (which is nearly the total loss) is lower.

If you introduce a dielectric material (other than air) between conductors, the characteristic impedance drops and the velocity factor increases, due to the same effect. Only in that way are they related in a ladder line.

In a coax cable, some of the plastic insulation is sometimes replaced by gas or air to make "foamed" dielectric cable, or by other devices such as plastic disks or a helically wound plastic string. This reduces the effective dielectric constant of the cable, which if the dimensions remained the same, would raise the characteristic impedance. It also increases the velocity factor. In those cables, the characteristic impedance is lowered to its nominal value by increasing the diameter of the center conductor. That is, for a given cable outside diameter and Z0, a cable with more air and less plastic will have a larger center conductor. The larger conductor reduces the I^2 * R loss by decreasing the R. So foam dielectric cable and others having a high velocity factor have lower loss than solid dielectric cables with the same OD because the center conductor is larger.

At a frequency of about 1 - 10 GHz or so, dielectric loss begins to dominate, and different relationships exist.

The equations describing the relationships among dielectric constant, velocity, impedance, and loss are simple and can be found in a great number of texts. I'm sure they can also be easily found on the web.

Source record: 79596

I've noticed, (but have not studied), some loose relationships in transmission line characteristics (and I guess waveguides fit in here). From an observer's point of view, it seems that a high characteristic impedence line (like 400-ohm or 600-ohm ladder line) also is usually a lower-loss line, and has a higher velocity factor.
It also seems that some coax may have a low VF and high loss.

Is there a real cause for the relationship of these 3 characteristics of transmission lines ? Is it something we can generalize ?
It makes some sense to say that the faster a signal gets through the line, the less loss it will have - and that gives some credence to the relationship in VF and loss being inversely associated.

235. Re: Gamma-Match formulas--design?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-05 02:41:57 UTC
From: John Smith <assemblywizard@gmail.com>
Message-ID: <d2sttnrcq1@domitilla.aioe.org>
Source record: 79600

To all:

Well, conductor diameter is not very critical in this configuration (or, at least that appears true to me--strange as that is to swallow.) However, the gamma rod I now have is #8 copper wire. And, that works out well, although it needs a couple of extra insulating spacers to stabilize it to the monopole, it is easy to work with and one only needs to solder it to the copper monopole, it can be bent and straightened at will to adjust spacings-shortened and lengthened by soldering on a bit.
Richard reminding me of the necessity of ferrite beads has made the tuning of gamma much smoother, and an swr of 1.4:1 is now had--coax length changes are MUCH less noticeable--bordering on trivial.
As it stands now, it is 32 ft. to the bottom of the monopole. The very bottom of the monopole is connected to the aluminum mast, the mast is well grounded (static and lighting protection are a given.) The monopole is now in the configuration of a 1 wave folded monopole (end fed through a gamma.) Placing the gamma in the middle of the two vertical lengths of the monopole (at the bottom end of the open "U") seems to give a complete 360 degree EVEN pattern, no noticeable bumps (perhaps a very slight elongation of the lobes in the same plane as the two ends of the folded monopole.)
From my simple observations, I put the most weight in s-unit readings of known signals I RECEIVE with a known transceiver and coax (this I consider to be the most "real world" test I can devise.)
This configuration is, by far, the best I have had sitting on that mast. It blows away the 1/4 wave I constructed (I am too worn out to put back the 1/4 and note the exact differences, but a safe estimate is 4+ s-units on all known received signals here on the valley floor. This has to be a low pattern, but critique and comments are welcomed to contest this.)
It might be my imagination, but there seems a very "solid" sound and feel to signals (this is impossible to measure and will make many--if not all--doubt my sanity!)
As some have noted, the humble s-unit will vary widely on transceivers, and is fallible...
However, now I have an antenna of a, somewhat, seemingly unique configuration which will give me a good conversation piece to chew over with friends....
I am pressing this antenna into everyday use while I throw another together to toy with the gamma on.

One more thing. I have found a beacon on 27.125 (Chicken Band Channel 14.) It is on the air 24/7. It is a 20 MW child's walkie-talkie with a 9 ft. antenna. It repeats the letters (call) "AOH" repeatedly at 7 wpm. I have had email correspondence with the operator "aoh@computermail.net", the above details gleaned through such.
He/she claims it has been heard throughout northern and central California,

and that it is located high atop Mt. Diablo here in California.
It has been an asset in testing the antenna(s) in receive conditions, under varying conditions, in "the real world."

Summary and conclusions:
-The gamma can be used to match a 1/2 wave end fed monopole with acceptable results.
-The gamma can be used to match a 1 wave end fed folded monopole with acceptable results.
-The 1 wave folded monopole seems a superior element to use in this design.
-Although only suspicion at this point, I suspect the gamma to be of slightly less "lossy" performance than the L-Match previously used and/or provides a more favorable "launch" to the radiation pattern desired--more attention needs to be given this in future experiments. The experiments continue.

Thanks all for your past and continuing assistance and council...

Regards,
John

Art, KB9MZ wrote:
"O.K. Reg, I`ll take you up on the 50 dB F/B."

It requires good balance for such cancellation.

Kraus gives the gain for a 100-meter dish near Bonn, Germany on page 676 of the 3rd edition of "Antennas". Gain is a function of frequency and varies from about 48 dB at 300 MHz to about 98 dB at 150 GHz. I don`t know if shielding has been added to make this a "high-performance" dish but I would wager that this enormous radio ear and mouth has an excellent front-to-back ratio. Probably exceeds forward gain at some azimuths and elevation angles.

Arnold B. Bailey has a lot to say anout a "connected" (driven) element and a parasitic reflector, starting about on 447 of "TV and Other Receiving Antennas", Bailey says:
"The optimum spacing for highest gain of a parasitic reflector is S=0.15 wavelength plus or minus 0.025. Here the relleector is operated at Q=+1 (longer than resonant) and the gain in direction 1 is approximately 5.5 dB. Reasonable compromise for a less critical system is to use a spacing of 0.2 wavelength and a parasitic element longer than resonant (at Q=+1). This case gives a gain in direction 1 of 5 dB."

On page 440 Bailey says: The front-to-back ratio ---is 17.5 dB in this case, and the Y/X ratio only about 9 dB, where +X represents the optimum direction.---" A picture is worth 1000 words.

Best regards, Richard Harrison, KB5WZI

Absolutely! While you might get some very deep nulls at some particular points in space, and fairly deep nulls in some particular azimuth/elevation angle combinations, they're not likely to be exactly as deep or in the directions the program reports. Gain, on the other hand, can be strikingly accurate in many cases.

Put together any model you want with an extreme F/B ratio. Then fiddle the model just slightly -- change the frequency, element length or diameter, etc. Look at how much the gain changes, and how much the F/B changes. Modify it more, and look again.

You'll see that the F/B is *much* more critical than gain. You can goof up the model -- or real antenna -- a lot more without any appreciable change in gain than you can before seeing major changes in F/B.

The reason is simple. To get a deep null and therefore good F/B ratio, you have to add the fields from all parts of the antenna together to get zero within a tiny, tiny fraction of a percent. If any one of the fields changes just a tiny amount, they no longer sum precisely to zero. But small change like that won't noticeably affect the gain. No model is good enough to precisely predict extremely deep nulls -- there's always too much difference between the model and reality.

I don't recall what Reg recently said, but I've gotten 50 dB and greater F/B ratios from an array by adjusting the phasing network while listening to a receiver placed in the null direction. But the null is that deep only in that direction, at that height above ground. It's also noticeably shallower a little ways away even in the same direction, because I've compensated for re-radiation from nearby objects, too. Even coax shield leakage becomes a very noticeable factor. So while I can tweak an array to get a very deep null, there's no way I can expect that to hold when anything changes, even just a little. I'd even expect it to change from day to day as the ground moisture changes and the sap rises in the trees.

Obviously 50 db is hard to get but is it beyond the realms
> of possibility?

For what, one particular azimuth/elevation combination at one single frequency? You might be able to do it. But it would be only of academic

interest at best.

Yes, it will not come by accident but Reg has said that 50 db F/B is
"silly"!
Why would he say that without back up evidence? He also did not offer
a max F/B that was obtainable in theory. I have seen computor results
that offer > 50 db F/B based on NEC, Can I trust gain if F/B cannot
be trusted? Obviously 50 db is hard to get but is it beyond the realms
of possibility?
The F/B that you offered is a bit unfair but then it is an antenna and
Reg did not qualify his statement.
I personaly modelled a antenna that comprised of a driven element
with the remaining elements acting as reflectors only. And we all know
that extra reflectors are a waste of time for H.F.(grin) but they do give
very high F/B figures.
I wonder what a corner reflector antenna would provide

Just for the sake of curriosity: what if a RASER "Radio (frequency)
Amplification by Stimulated Emission of Radiation" device existed?
50 db would become acceptable and common place overnight, huh? MASER's
exist, why now long wavelength? Sure the antenna at HF would be the size of
the pentagon, but Bill Gates wouldn't blink an eye! <grin>

240. Re: VF, low-loss line, high-impedence line - relationship

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-05 04:57:43 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <d2t5s7oam1@titan.btinternet.com>
Source record: 79605

The relationship between the three characteristics is more imaginary
than real. It amounts to little more than an old-wives' tale.

The reason attenuation is usually smaller for twin line than coax is
because the twin line conductors are usually of greater diameter than
the coax inner conductor.

And the reason twin line usually has a greater velocity is because the
conductors are spaced further apart and usually there's less
insulating material between them.

But it's quite easy to reverse the situation by obtaining large
diameter, high impedance coax and flimsy close-together twin line.

Reg, G4FGQ

When I was working with antennas, we considered the antenna's F/B ratio
used the max of the front compared to the max of the back. But, I get the
impression that the rules are different now.

That makes perfect sense. Just like for power lines - higher voltage means less loss over the same line. I need to try to use ohms law a little more often. I've wound impedence matching transformers myself - without even thinking about the fact that I was also increasing (or decreasing - depending on the flow) voltage.

thanks

What are "front" and "back"? If the maximum forward lobe is +10 dBi at an elevation angle of 23 degrees and the best null is -30 dBi at an azimuth angle 160 degrees from the peak forward lobe, and at an elevation angle of 47 degrees, are you saying that by your definition the front/back ratio is 40 dB? If so, I guess that's interesting but I can't imagine what it might be good for.

Who's "we"?

****
Does that mean that more insulaton material between the conductors decreases
the velocity factor ?
Ok - its making more sense. Ladder line just happens to have a high VF and
low loss - each for different reasons.
****

Another height-related factor that may be worth considering is the effect of surrounding the lower part of the antenna by nearby buildings. Inside a typical 2-floor home are 3-D grounded meshes of electrical wiring and (in many countries) central heating pipes. The wiring mesh typically extends up to 6m/20ft above ground, which may be a significant fraction of the antenna height.

For example, in the suburban situation here, the lower part of my vertical for 40m was almost completely surrounded by these "scattering objects" at distances ranging from 0.5 to 2 wavelengths. I never got around to modeling the effects of these objects... though someone could easily try it.

I make no claim to being qualified to discuss antennas with you when we are in disagreement. I worked as an antenna design engineer for 15 years till 1968 when I was layed off from TRW. I was never a high level theorist but managed to hold a decent position with designing hardware. I did work with some highly qualified engineers from whom I thought I obtained alot of knowledge about antennas. Thats why I was bold enough to say "we". I still maintain a casual relationship with George Oltman who you might know from his association with antenna groups with IEEE.
As for the F/B, I considered that to identify Front to Back of the antenna's radiation pattern. I would consider it appropriate to identify the radiation toward the "Front" as the max radiation to the front. Then, it seems that the numerical level used for the "F/B ratio" should be max to the Back.
I make no argument that this definition I use is *the* way F/B is. But, dont we define "side lobe level" as the ratio of the main beam Max to the side lobe Max? Be aware, I dont write to correct your thinking. I did consider the F/B to be flawed when the main beam Max is compared with a rear radiation Min.

I'll consider myself corrected and stop posting.

Bob:

You are on the right track; a process of elimination is often the fastest way to identify the noise source. But don't underestimate the wonders of seemingly prosaic household systems. Microprocessor controllers are everywhere, from your washing machine to your sprinkler controllers to your furnace controls. And that's just YOUR house, your neighbors all have their own sources to add to the general noise level.

Try a battery-powered AM radio, tuned between stations. See if you can locate the noise with the built-in directional loopstick antenna. Even if the noise is being radiated from a number of powerlines, you can still try cutting power for your entire house. OTOH, some gadgets will have battery backup, so, like my sprinkler controls, the microprocessor keeps right on running even when I cut off the power.

Neighbors are notoriously uncooperative when you suggest cutting off the power to their house while you search for RF noise.

249. G5RV Balun ?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-05 09:04:47 UTC
From: Gary
Message-ID: <1lk451h1t0e9cpg3ssf3egqolpkombrnnt@4ax.com>
Source record: 79614

I've looked at several commercial G5RV's and most seem to lack a balun when the coax is connected to the 450 Ohm ladder line. I would suspect a 4:1 balun at the coax to ladder line connection would make for a better operating antenna or perhaps running the ladder line into the shack here to the 4:1 balun built into my tuner. Though the normal length of the ladder line coming off the G5RV may not be long enough to reach my tuner, much less the problem of keeping it away from the aluminum siding, tower etc. Would my best bet be to get a 4:1 balun and feed that one end with coax and the other end with the ladder line of the G5RV ?

Any input appreciated.

Thanks in advance !

73 Gary

I am surprised that you would favor the person-to-person model, since you appear to be willing to ignore my two attempts at conciliation and appear to enjoy remaining in a self-aggreived condition. As you point out, certain attitudes in certain places can earn you the flat-face award, and you seem to be a determined candidate.

One of the hallmarks of wisdom is knowing when you are being insulted and when you are being presented with an uncomfortable reminder of your condition. As an Extra, do you really think that a ham should be surprised to find that an arc-discharge luminary, placed in proximity to his rig, causes RFI? I hold a ham to a slightly higher standard of understanding of RFI than I would expect of the general populace. RF noise is a very basic part of the RF communication hobby known as ham radio, so just how low should the bar be set for understanding of the basics of your hobby? If the basics are too challenging for you, then perhaps you should either get smarter or live within a less demanding cohort. And just what electronics hobbies could those be? CB radio certainly comes to mind; a venue of zero examinations and largely technically incompetent appliance operators. And below that, cable TV, where the two big challenges are finding the power button and a channel.

Your functional competence in communicating within Usenet is also deficient, as you sent a redundant copy of your post to my personal address. Please try to learn the difference between replying to a post in a newsgroup and

replying to the poster's address (especially when the poster affords you the courtesy of a non-spoofed address). I find it amusing that you deem I should get TWO copies of YOUR post, while you publicly declare that my posts are unfit for your attention. Further, your declared existence in this group, that you "read this newsgroup only in hopes of learning something every now and then", is selfish and parasitic. Usenet is a participatory forum, and you should try to find satisfaction in contributing as well as in taking.

Finally, I don't know if you intended pithy sarcasm, or simply displayed further evidence of senility, by signing your missive with a "73". After insulting my intentions, you close with the generally accepted icon for "best wishes" or "cheers". Thank you for the complete reversal of your entire thought process in the space of one line! I must assume that the closing salutation must have been appended AFTER you took your daily meds.

Hi Gary,

The impedence at the input end of the twin lead is low on most bands , thus there is no need for and impedence transformation at that point. A 1:1 Choke balun is a good Idea to keep RF off the Sheild of the Coax. But I've used the G5RV both with and without a Choke and they both will will quite well. If you put a 4:1 balun in the system you will be bringing the impedence down to about 17 ohms on 20 meters for instance. not a good match to 50 ohm Coax. The best thing would be to bring the Ladder line all the way to a balnced tuner in the shack. But the one with coax will work quite well Especially on 40 & 20 Meters. There is a lot of info on the net about the G5RV some good Some questionable.

hope this helps 73 , Dave KC1DI

Thanks for your comprehensive, civil analysis. It appears either that my incarnation of NEC-2 doesn't deal with this situation properly, or I didn't use it right (the latter is more likely). I'll have a look into it.

> In all the cases I looked at, however, the 5/8 wave vertical
> did show some gain over a quarter wave vertical up to at least 14 degrees.
> ...Over average ground, the gain difference is at or just above 3 dB up to
> about 10 degrees.

... which supports my contention earlier in this thread: The peak gain increase between a 1/4-wave and a 1/2-wave or 5/8-wave vertical is 3dB above the gain differences of those antennas as dipoles of _twice_ that length in free space.

Repeating the reasons for this...

* the electrical length of the vertical is doubled by its image below the ground plane (a 1/4-wave vertical monopole becomes an electrical 1/2-wave dipole)

* the peak "free space" gain of the monopole and its image is increas-
ed 3dB, because all radiation from it is confined to one hemisphere (above the ground).

I agree Roy, I did say it wasn't easy and I suspect you are correct if the
null is "deep"
But if the general" Front to rear"is exceptionaly good then
there is no reason for the F/B not to fairly accurate.
I certainly would not call it "silly" which is exactly
how "old wives tales" start.
The particular case I was referring to was where multiple
reflectors were used to dampen rearward radiation to a minimum.

One old wives' tale (*not* attributed to Roy) is that ladderline has
lower loss than coax (given as a blanket statement). Therefore,
laderline is "good" and coax is "bad."

However, compare something like Andrew LDF4-50 to Wireman 554 and you find that the "lossy" coax has a loss of 0.48 dB/100' @ 50 MHz and the "low-loss" ladderline has a loss of 0.41 dB under the same conditions.

Hi Bob ..... wherein lies the "nut" in this whole conumdrum. These RF generating devises should not even be on shore. I think that Great Britian still has, or in the past, a very strict set of rules regarding devises. Proper engineering, with I venture to say minimal cost, would clean up things significantly. Even if every ham had an EE and thoroughly understood every detail of this problem ..... what would we do with Mrs. Jones next door or better yet in the next apartment. As Ed had mentioned some are not too responsive to having us bypass the speakers on their new 5K$ electric organ.

Some G5RV manufacturers know that most hams don't realize they
need a balun and a balun increases cost and decreases profit.

> I would suspect
> a 4:1 balun at the coax to ladder line connection would make for a
> better operating antenna or perhaps running the ladder line into the
> shack here to the 4:1 balun built into my tuner.

Nope, a 1:1 current choke is what one needs. For instance, the
resonant impedance at the coax/twinlead junction on 80m is about
10 ohms for a 5:1 SWR on the coax. A 4:1 balun would take it to
2.5 ohms for a 20:1 SWR on the coax. A 4:1 balun at the coax to
twinlead junction makes a G5RV worse, not better.

Jerry Martes wrote:
"When I was working with antwennas, we considered the antenna`s F/B ratio used the max of the front to the max of the back. But I get the impression that the erules are different now."

Front-to-back ratio is defined as the ratio of power gain between front and rear of a directional antenna.

A.W.P. King writes on page 209 of "Transision Lines, Antennas, and Wave Guides"*:

"In practice, it is usually important to maximize the ratio of forward to backward field or the ratio of backward to forward field. If the ratio of forward to backward field is maximized, the parasite is called a reflector; if the ratio of backward to forward field is maximized, the parasite is called a director."

I don`t think the above has changed since 1945.

Best regards, Rihard Harrison, KB5WZI

Thanks, Wes-- when originally considered it was looking at the moon
in terms of approaching a point source (the surface of the moon
being relatively small TIME-WISE- but the surface to the edges
being relatvly HUGE in distance , per Wavelength would allow a
distortion of a reflection. As I said , its dangerous to get me
thinking too hard (I tend to fall asleep)! Tho, hadn't considered
the (Cheezy) effect! makes me wonder if linear circular would be
the way to go, or would it distort as bad as other signals
(do to Faraday Rotation- the skewing of the signal's polarization)?
Just curious. The linear circular refers to circular yagi construction
rather than as a Helix? Or is this tilting at windmills? Jim - NN7K

Hi Jerry ....there would be absolutely no reason to tell you do anything concerning the above post. I look upon the newgroups in a positive way to share information. I have drawn ire from some in the past but maybe those individuals will think the next time they hit the send key. There are plenty of people who follow these groups who don't send messages and I feel a good part of them are young people who are interested. I remember those times as a teenager just starting out and being treated quite poorly by some OTers. We really need to remember what we were like starting out and the errors we made. As for getting yelled at ......you must be married ..... as my dad once told me ...the best 2 words are yes dear .... and boy he was right.

What "arc-discharge luminary"? The OP referred to a 120-volt halogen lamp, "no transformer". The standard, commonly-available consumer device which fits this description uses a tungsten filament in a halogen atmosphere - it's a simple spin on an ordinary incandescent bulb. There's no arc discharge involved in the operation of such bulbs, and in the absence of a switching regulator or dimmer I know of no reason why such lamps would be more likely to generate RFI than a standard incandescent lamp.

I see nothing in the OP's query to suggest that he was referring to a high-intensity discharge bulb, which would require a ballast of some sort and which could certainly generate RF.

>Your functional competence in communicating within Usenet is also deficient,

In defense of the gentleman to whom you are responding, I would point out that the convention of "post a reply to the public newsgroup or mailing list, and send a courtesy copy to the individual's mailbox" has been in use on the Internet for at least 15 years, and probably more. Some people like receiving courtesy copies, some dislike it, and I agree that one should respect the individual recipient's choice when it is known.

I do not agree that the poster was out of line or "deficient" in sending you a courtesy copy of his posting.

For what it's worth, Ed, my own immediate reaction to several of your postings was to conclude that they were unnecessarily contemptuous. I think that your advice would be more successfully received, and thus more effective, if it were delivered in a tone which was, shall we say, less snotty?

It works. Taken to an extreme, you have a grid-dish reflector.

Additional reflectors in the plane of the other Yagi-Uda elements don`t make best use of materials aloft. Placed ahead of the driven element, additional elements are in a strong field where they may work as directors to sharpen the forward gain. Placed behind the reflector which has already reversed most of the energy in its direction, a parasitic element is less effective as rhere is less energy to work with.

> ed 3dB, because all radiation from it is confined to one hemisphere
> (above the ground).

Remember, that's for perfect ground only (and maybe salt
water ground). If one buries half of a dipole in earth
ground, one loses most of that 3 dB to the ground.

For instance, EZNEC reports: The max gain of a 40m 1/4WL
vertical with 8 horizontal radials one foot above average
ground is -0.29 dBi. Raising the radials to one wavelength
above ground increases the max gain to +3.23 dBi. (Of course,
the 3D radiation patterns are not exactly the same but the
correlation to that 3 dB of image power is in there because
of decreased ground losses at increased height.)

Problem: Most everyone with a 1/4WL vertical and four buried
radials is throwing away about half of his/her source power.
Solution: Put up a horizontal dipole. :-)

Snip...

The type of lamp cord common in South Africa (don't know about other countries): Two conductors of 0.75mm^2 cross sectional area insulated with about 1mm of white pvc and a spacing of around 2.5mm has an impedance of aproximately 60 Ohms. Close enough to 50 to use for quick&dirty dipoles without balun or tuner. Though have no idea of the velocity factor and don't really need to bother as I just pull apart the cord until I have what looks like enough to get a good swr. Then fine tune by pulling more or cutting. A swr of about 1.3 is achievable.

Hi Wes, let's say I'm trying to choose between the two.
Wireman 554 is about 25 cents/foot. How much did you say the
Andrew LDF4-50 costs? :-) (LMR-1700 is about 8 bucks/foot.)

Here's another way to look at things for multi-band non-
resonant antenna lengths. The feedpoint impedance for
that type antenna may vary from a low of about 50 ohms
to a high of about 7500 ohms. To minimize SWR for all
conditions, Z0 should equal the square root of those
two values or 612 ohms. Given 600 ohm open-wire line,
the SWR shouldn't go much above 13:1 for the open-wire
line but may go as high as 150:1 for the coax. I don't
know about you, but I would rather run with a maximum
SWR of 13:1 rather than a maximum SWR of 150:1.

Hello,

The G5RV as you describe it is a farce!

If you have a balanced tuner (symetrical), ladder-line and two pieces of wire, you can simply construct a Levy antenna. It works great on most HF bands depending on the tuner's quality and you can even get the 160m band with 2 x 20m dipole and 15 to 17 m twinlead.

Generaly I can agree with that but it is NOT TRUE in all cases.

1 It can NEVER reflect all radiation from the rear
2 Coupling is reduced as the directors move away from the driven element
to the point where little current flows.!

A yagi does have an advantage in simplicity together with the ability
to "focus" the forward lobe but not at the expense of removing rearward
radiation.

This post is starting to be remoniscent of the old days where Guru's stated
that more
than one reflector was pointless and unproductive because they could only
think
Yagis to the ommission of all others . Need W8TI to complete the full circle
(On a prior post I brought up the corner reflector antenna but I had
temporarily forgotten
that the reflectors carried little current and thus could not be a good
contender
for high F/B)

Placed ahead of the driven element,
> additional elements are in a strong field where they may work as

HUM.... isn't F/B values retarded when maximum gain occurs?
This suggests that max gain occurs when there is MORE energy to
work with at the rear does it not?

of course ...

the G5RV is much the same as the double-zepp or doublet antenna !

if you have an antenna tuner with balanced line connector, you dont
need a balun ... just keep the ladder line 12.80m for current coupling,
or keep it 23.60m for voltage coupling. the legs will be 41m together !

this is proved antenna and it works very good from 160m to 10m !

> a ladder line.

Here's a slightly different way to look at the same thing Roy has said. For a given coaxial cable outer conductor diameter, assuming smooth copper conductors, there's a particular ratio of D/d (outer to inner conductor diameters) that gives you the lowest loss. So long as there's negligible loss in the dielectric, that D/d is independent of what dielectric you put in there. But since putting in a dielectric lowers the impedance, the loss goes up as a result of higher current for a given power level.

You can put numbers on it pretty easily. Assuming no dielectric loss, the attenuation of the line in dB per unit length is inversely proportional to the line impedance: dB/100ft = 4.34*Rt/Zo, where Rt is the total RF resistance of the wires. But Zo is inversely proportional to the square root of the relative dielectric constant of the dielectric in the line. Putting the two together, for a given conductor configuration (D and d in coax), if there's no loss in the dielectric itself and only loss in the resistance of the wires, the loss in dB/unit length is proportional to the square root of the net effective dielectric constant around the line. Since the velocity factor is inversely proportional to the square root of the same net effective dielectric constant, then for a given configuration of conductors, the loss is indeed dependent on the velocity factor, even with no power dissipated in the dielectric itself. This is true for coax and open wire line in equal measure. But beware that you are more

likely to have dielectric loss in open-wire line for a variety of reasons...

For lossless dielectric and a fixed conductor configuration (coaxial, two-wire, or other TEM line with fixed conductor sizes and spacings), varying just the dielectric, then,

dB/unit length = k1/v.f. = k2/Zo = k3*sqrt(net effective dielectric constant)

where k1, k2 and k3 are proportionality constants depending on the conductor configuration.

Cheers,
Tom

According to the empirical results of AM broadcast radiators, and also Roy Lewallen's EZNEC numbers in his last post in this thread, the ground plane itself doesn't need to be perfect, or maybe salt water to realize the gain improvement. It's just that a very low resistance connection to it must exist for the vertical to work against.

|know about you, but I would rather run with a maximum
|SWR of 13:1 rather than a maximum SWR of 150:1.

Who's talking about multiband non-resonant antennas? I prefer to
operate with SWR <= 2.0. I can bury my line, strap it to the tower,
run it through a hole in the block wall without heartbreak and the
only concern I have with rain is that we don't get enough.

Furthermore, I don't have concerns with breakage or degradation from
UV and the only tuner I need is the one built into the plate circuit
of my Drake L-4B.

Point is, it has to be near perfect. 4 buried radials just
won't hack it.

Usually, anyone considering ladder-line for the feed
system. If the antenna is single-frequency with a 50
ohm feedpoint, there's not much of a reason to even
consider ladder-line except for very long runs.

"Can you tx on a tv antenna?"

A perfectly matched TV receiving antenna reradiates 50% of all the energy it intercepts. A mismatched antenna retransmits a higher percentage.

I used a small TV antenna, fed with 300 ohm ribbon through a homebrew 1/2 wave coaxial balun made from RG-11/u to make a 4 to 1 jobber. Worked great with my Ten Tech transverter on six meters.

Years ago I did a similar trick with 2 meter AM phone and another type of TV antenna.

So the answer is yes....however...now a days you normally find 70 ohm TV coax and a balun up on the antenna. That Balun will not take much power. Ten watts not a problem, over that....well. And you won't need a balun. Just hook the coax to the rig. Take the slight SWR and don't sweat it.

BUT again....most to all TV antenna's are NOT cut to the ham bands.....

Linear circular is an oxymoron. When you phase two crossed Yagis to
generate circular polarization, it is just as "circular" as a helix.

It's been 20 years (how time flies) since I was operating EME but I
remain interested. There is a current school of thought that
switchable polarization has an operational advantage. I remain
unconvinced when the complexity and degradation of performance is
factored in. I don't know of anyone who is using true circular
polarization (at VHF) even though their antennas are capable of
generating it.

The reason to have switching capability is speed up the QSO. With
fixed linear polarization, at any given time, there can be spatial and
Faraday rotation caused polarization mismatch between two stations
located on different parts of the Earth. Switching polarization at
one end can overcome all or part of this mismatch. Usually, if one
waits long enough the always changing Faraday rotation will bring the
mismatch to zero or near zero without any switching.

So there is a trade of complexity for speed. In the modeling I've
done, I have yet to see a case of high gain, crossed-element Yagis
that were not degraded by the presence of the stacking hardware.

find that the field strength is 3 dB higher, and the
> power density twice as great,

That's interesting! That part regarding change of "density"
How does one determine the density changes in various parts of a radiation
pattern?
Does the Laws of Partial Pressures apply?
Does high density radiation penetrate the earths layers more than low
density
R.F. radiation before it returns to earth? If R.F. has density then it must
have mass
thus gravity can return radiation to earth at odd places on earth. Grin

I've been away today and just discovered several postings I'd like to comment on. I'll be in and out for the next couple of days, so won't be able to carry on a very immediate conversation. I'll comment on this one first.

The attenuation characteristics I've been talking about (attenuation of primarily the low angle signal) isn't affected substantially by normal ground systems. It's due to reflection from the ground well beyond the boundary of typical radial wires. Increasing the number of radials will improve the efficiency, which increases the size (actually, strength) of the resulting pattern but not its shape. The ground reflection phenomenon alters the shape, and this shape modification is a strong function of the ground constants and frequency. Nothing you do with a ground system of normal diameter will bring back that low angle radiation. You need to move to the beach or go maritime mobile to get it.

When you model using a MININEC-based program or use EZNEC's MININEC-type ground, you're seeing only the pattern modification due to ground reflection. The ground system loss (that is, I^2 * R loss for currents returning to the feedpoint via the ground) for that ground type is zero, unless you intentionally insert a resistive load at the base of the antenna to simulate ground system loss.

> . . .

Yes, this is something I didn't mention and should have. My statement about the negligibility of dielectric loss below 1 - 10 GHz is strictly true only for coax with decent (common) dielectric material (e.g., PE or PTFE). When the impedance is higher, as it is with ladder line, the effect of the dielectric loss is proportionally higher. On the other hand, a good part of the ladder line field is in the air (although it's most intense directly between conductors, where any insulation typically is), which reduces the effect of loss in the dielectric.

Many years ago I measured the attenuation of some common 300 ohm TV twinlead, and found that in some cases when wet its attenuation could exceed that of RG-58 coax. The extra loss is intirely due to degradation of the quality of the dielectric between conductors. See http://eznec.com/Amateur/Articles/Portable_Feed_Lines.pdf. I know Wes has done similar measurements on window line and has posted the results at his web site; perhaps he'll remind us again of the URL.

Things seem to be getting a little confused here.

When you replace a free space environment with a perfect ground plane, the *average* field strength of *all antennas* increases by 3 dB for a given power input because of the reduced volume. This shows up as a 3 dB gain increase when the gain is referenced to a free-space antenna such as an isotropic source. No antenna is given any additional advantage over any other - they all get the same amount of increase. So if I read the above statement correctly, it's not true. The gain increase between a 1/4 and 1/2 or 5/8 wave antenna over a perfect ground is the *same* as the gain increase between a 1/2 and 1 or 5/4 wave dipole in free space. Not 3 dB greater. If you'll look at the patterns of the antennas, you'll find that the pattern of a 1/4 wave vertical over perfect ground is identical in shape to half the pattern of a 1/2 wave free space dipole, but 3 dB stronger. Likewise for any other vertical and its twice-as-long free space dipole counterpart.

When the perfect ground is replaced by real ground, an attenuation factor is introduced which actually changes the pattern shape. This pattern shape change is different for each height of vertical because it depends on the angle at which the radiation from each part of the antenna strikes the ground. The different antenna heights have different current distributions and so different fractions of the total radiation hits the ground at different angles. The effect of the attenuation at each elevation angle depends on the ground constants and the frequency.

You're probably more used to looking at surface wave attenuation, where this ground reflection effect doesn't exist. Instead, there's a single frequency and ground dependent attenuation that's essentially the same for all antenna heights. What I'm talking about here is sky wave radiation which consists of both a directly radiated "ray" (which undergoes no attenuation other than that caused by its expanding volume with distance) and a "ray" reflected from the ground. It's the attenuation and phase shift of this second "ray", which depends on the elevation angle, ground constants, and frequency, which causes the pattern shape modification and attenuation of low angle signals. If you look into the way NEC-2 operates you'll see that it does just this calculation. The relationship of the reflected ray before and after

striking the ground is described by a fairly simple reflection
coefficient, which is quite different for horizontally and vertically
polarized waves. If you assume a current distribution, it's not
difficult to calculate the pattern manually. The reflection coefficients
can be found in Kraus.

> Repeating the reasons for this...
>
> * the electrical length of the vertical is doubled by its image below the
> ground plane (a 1/4-wave vertical monopole becomes an electrical
> 1/2-wave dipole)

I don't think that's a good use of the term "electrical length". It is
true that the radiation pattern of a 1/4 wave vertical over perfect
ground (but not imperfectly conducting ground) is the same as that of a
half wave dipole in free space. Also, its feedpoint impedance assuming
no loss is exactly 1/2 that of a 1/2 wave dipole in free space.

>
> * the peak "free space" gain of the monopole and its image is increas-
> ed 3dB, because all radiation from it is confined to one hemisphere
> (above the ground).
>
Yes, but this is altered if the ground isn't perfect. When the ground
isn't perfect, the shape of the pattern of the monople is no longer the
same as half a free space dipole, so the gain difference is no longer a
constant 3 dB at all angles. Some of the radiated energy is lost in the
ground reflection, and the fraction which is, depends on the angle at
which it strikes the ground.

Source record: 79562

A good fraction of your power is lost to the ground even if you have a perfectly lossless ground system. To find the amount, use EZNEC (the demo program is perfectly adequate), select MININEC-type ground and appropriate ground constants. Set the plot type to 3D and run a pattern calculation. The "Average Gain" reported at the bottom of the main window is the loss due to ground reflection. Short of making a ground screen several wavelengths in diameter, all you can do to improve this is to move to a location where the ground is more conductive.

For example, the example file Vert1.ez shows a loss of over 5 dB in the total radiated signal.

Ground reflection loss applys to horizontal antennas, too. But with horizontal antennas it primarily attenuates the very high angle radiation, while with verticals it gets the low angle radiation. You can easily see its effect by superimposing a plot calculated with perfect ground over a plot calculated with MININEC-type (if there's a direct ground connection) or Real, High Accuracy(*) (if there isn't) ground.

(*) For NEC-2 users, this is EZNEC-speak for Sommerfeld ground. Reflection coefficient ground doesn't provide any real advantage with modern computers, so it's no longer an option in EZNEC. In v. 3.0 and earlier versions it was called "Real, Fast Analysis" ground.

I've heard that lamp cord was low-impedence but had forgotten what the
impedence was.
Do you just use some tape once you unzip the length you need - to keep it
from self-zipping from the tension?
I also heard it had a pretty high loss - But like you say - for a quick-and
dirty antenna and feedline, its a good trick for a ham's bag.
Thanks for the info.

> It works. Taken to an extreme, you have a grid-dish reflector.

No, No, No Richard! I do not

A grid-dish reflector is where the reflector assembly has voids in the
reflector panel
that R.F. cannot penetrate. A similar instance is the perforations in a
transmitter housing.
Maybe it was the term "dampen" that led you to think I had a "grid" type
reflector which is not the case.
My antenna consists of 8 - 1/2 wave elements of which one is fed. All others
are resonant reflectors
set on a parabolic curve as is the driven element, thus it does not
"focus".This can be
fabricated using standard straight dipole elements . Advantages are to be
had using elements
that are "shaped" to minimise "reactance" coupling and also the physical
turning radius.
It is this variation that I am building now to see if it becomes quieter
especially when static is around.
It is times like this that light telescopic fishing poles can be used to
advantage together with
aluminum tubular mast. You may remember that I sent a 60 foot boom yagi
picture to you
years ago with 13 elements (26 fishing poles) which was also light weight
and thus desirable
when testing or experimenting to find out where the knoweledge envelope can
be pushed.
Regards
Art

Hold on. Those are "Loop Yagis." They are not circularly polarized
any more than a quad is. When an approximate one-wavelength loop is
fed at the bottom, it has linear horizontal polarization. Period.

If they make a coax as low-loss as ladder line, I'll concede you that - but
then:
Could we agree that ladderline (or window line - or twinlead) has these
characteristics:
1. Ladderline (or twinlead or windowline) costs less than an equal length of
low-loss coax .
2. The weight of the ladder line would probably be much less than the weight
of an equal length of low-loss coax.
---Well, sir - that sells it for me. I'm a cheapskate and I don't like the
coax loading down the dipole and stretching it from all that weight. AND I
like to play around with something other than the 50-ohm ho-hum stuff.
Ham-nerd is a good word, I think.

From all the responses, I got a lot to think about. Thanks.
I got the impression that resistance in the wires is the main cause for loss in a transmission line.
NOTE: I recall some line having much higher losses at higher frequencies.
(so substitute x for R ??)
Another note - I noticed some coax has different capacitance rating per ft. depending on the type and brand, etc.
(I thought about using a length of coax for a capacitor in a trap at one time).
Question: could some of this loss be caused by the capacitance in the line ?

You can make a very good HF common-mode choke by deliberately resonating the inductance of a coil of coax with its self-capacitance... so it seems to follow that a resonant UHF common-mode choke can be made by tying the coax into exactly the right knot.

Don't know if it's of any practical use, but it isn't a completely April Fool idea.

Please don't consider yourself unqualified. I don't think anyone posting on this newsgroup should, and with your background you certainly shouldn't.

My question about who "we" meant was to establish a context for the definition you used, which you've supplied -- thanks.

The definition you use isn't a bad one, although it might not be the most useful, provided that you restrict the analysis to free space and are speaking only of a single plane of the 3D pattern. This is commonly done in discussing Yagi arrays, for example. Perhaps your experience was largely in Yagi, log periodic, or other planar arrays which lend themselves to this simplification. The meaning of "back" is open to some interpretation, though. Sometimes it means the precise direction that's exactly 180 degrees from the main forward lobe. Sometimes, though, it refers to a range of angles, even as great as the whole rear semicircle. Let me give an example. Suppose an antenna nominally has a deep null directly to the rear of the front lobe. But a slight asymmetry in the antenna moves the lobe a few degrees to the side. This could easily degrade a strictly defined ("rear" meaning exactly to the rear of the peak of the front lobe) front/back ratio by 10 or 20 dB. It's hard to conceive the application where it would really change the usefulness of the antenna. But a very slightly asymmetrical antenna would look much worse on paper. In your experience, would you consider this to be a poor f/b ratio, or would you give the definition some slack and allow "rear" to vary a few degrees? If you'd give it some slack, then the next question is how much -- could the null be skewed 5 degrees? 10? more?

In my limited experience, when the second convention is used (allowing the whole rear semicircle to count as "rear"), the "rear" figure often comes from the largest lobe in the "rear" region. So the gain in the precise direction opposite the front lobe doesn't matter, if there are lobes in other directions in the rear semicircle. This definition would be useful for amateur beam applications, because it tells you the minimum amount of attenuation you'll get from signals coming from any direction within the rear 180 degrees of the pattern. Who cares that you have a 50 dB null in one very narrow direction, if a few degrees away the response is 40 or 50 dB greater. The definition of front/back ratio seems flexible, sometimes used to make the measure more meaningful or useful, but sometimes, I'm sure, to obscure the quality of the pattern.

In the example I mentioned in my earlier posting, though, of the complex pattern of an antenna over ground, the definition can get muddy indeed. So it's often necessary to carefully define the term and state exactly what you mean if you really want to communicate meaningful information when you quote a "front/back" ratio.

There is no power loss in either pure capacitance or pure inductance. There is loss only in the resistive (or conductive) components: the RF resistance in the wire and the RF conductance in the dielectric. It is fundamental that the inductance and capacitance in a TEM transmission line are just what cause the energy to propagate from one end to the other...or I suppose if you view it at a higher level, you could say that the same fields which yield the effects we call capacitance and inductance also cause the propagation of energy when they result from a TEM transmission line configuration. I'm sure other valid ways of looking at the situation exist too. (I should also mention that there can be some power lost to radiation, but in most cases that's quite small.)

Increased loss at high frequencies comes from several sources: smaller skin depth at higher frequencies means higher resistance in the wires. That goes up as the square root of frequency, once you get to a skin depth which is small compared with the thickness of the copper. Higher frequencies result in higher dielectric loss, though that's generally not an issue below a few GHz. But imperfections along a line can cause significant attenuation because of multiple reflections; dozens of small reflections can add up to a big problem.

Cheers,
Tom

Cheers,
Tom

> Question: could some of this loss be caused by the capacitance in
the line ?
>
==========

Yes. It's another way of looking at it.

In addition to current in the load, there is a current which flows between the pair of wires through the capacitance.

Increase the capacitance and this current increases.

There is negligible loss in the capacitance itself.

But the capacitor current has to flow along the wires to get there.

And so the additional capacitor-current loss actually occurs in the wire resistance.

But this is just the same as saying that loss is greater because the impedance Zo is lower (due to the increase in capacitance).

The opposite effect occurs by increasing inductance. An increase in inductance increases Zo and so much reduces attenuation. That's why 88 mH inductive loading coils were used at intervals of 2000 yards at audio frequencies in very long telephone cables. An invention of the great but modest Oliver Heaviside which I think somebody else patented and manufactured by many millions.

88 mH loading coils, spaced at 2000 yards, increases Zo from about 300 ohms to 1100 ohms, thus reducing loss in dB per mile to about one third.

Reg, G4FGQ.

You are right there is a connection between wire diameter and spacing.
It has to do with the self inductance and resistive losses of two
conductors in proximity. By contrast a balanced line has a wider
spacing and also allows part of the energy to travel unhindered, so to
speak. It helps if the balanced line is designed to be close to the
theoretical impedance of free space. The price to pay is that it is
more susceptible to the environment. The loss in coax is a trade off
to achieve stability.

In a perfectly matched system, half the power is "lost"
in the source. In the case of a receiving antenna, that
power is lost to radiation from the antenna during
receive, i.e. the antenna radiation resistance is the
"source".

Something I have wondered about: If we simply amplify
the receiver voltage through a near infinite impedance
FET with virtually no load on the signal, do we get the
signal information but lose virtually all the power to
re-radiation? (assume high S/S+N)

Jeeze. You use an rf densiometer of course.

Cecil
Good thought. As I understand it a receiver doesn't really need any power, so if the antenna is 50 ohms and the Rx input is say 1000 ohms most of the power has to be relflected to the antenna.

i am currently enstalling a 46 foot twin verticle, 2 46 foot verticles only inches apart, that are connected together at the bottom with a single lead. The top of each verticle is connected to 500+ feet of copper wire that is arranged in an irregular circle with about 5o feet separation of each end point. One end is the feed with the same wire carefully brought into shack without touching structure. I used an insulated sink (or toilet not sure) tube with copper inside and fiberglass covering. I am hoping the shielding will keep TVI down? The average height of the wire is at 50 ft so basically I spliced the verticles into the rombick shaped longwire. Reception is great but I have a couple of tests and tweaks to do today before I am willing to put a load (rf) on the wire. I will report back as soon as I get some numbers. 73 Scotty ke5to

I think so, yes. Electrically, a "driven element" which feeds a
very-high-impedance FET would look like a simple passive element (e.g.
like a parasitic director or reflector in a Yagi). There would be
some small amount of power delivered into the load (the FET's gate
capacitance and its associated losses), and some small amount
dissipated as losses in the element itself, but the rest would be
re-radiated... just as is the case with an unloaded parasitic element.

An alternate method is to put some of the RF into a water-tight and RF-tight box -- a great application for one of those ammo boxes left over from survivalist exercises or just plinkin'. Drop the box into a tub of water and see how much the water level rises. Then open the box and let the RF out. (Be sure to wear safety glasses. A shielded cod piece isn't a bad idea either.) Repeat the measurement. You can then calculate the power density from the difference between the amounts the water level rises.

A takeoff on this method would be to leave the rf in the box and
measure the temperature rise of the water. This eliminates the need
for the cod piece.

I'm really surprised that "The 'ole Metrologist", Richard Clark,
didn't already jump in with this.

Cecil,

Check with Melles-Griot on this one.

Hint: Think conservation of energy. Them joules gotta go somewhere.

However, in reality the opposite happens. As the antenna load goes to
infinity the scattering cross section (i.e. retransmission) goes to zero
faster than the capture cross section.

(Plagiarized from Kraus Antennas, 2nd ed.)

I knew I was confused about what you were trying to do.
If you just tilt the horizontal dipole to a vertical
position, it will still be center-fed. Are you trying
to gamma-match a 1/2WL vertical base-fed against a
radial system? If so, try this EZNEC file:

To be fair, Art did have a smiley face farther down. The
units of the Poynting Vector are e.g. joules/sec/meter^2.
That's a power density and is the same as "irradiance" in
the field of optics.

Make it one megohm and virtually all receive power in
a perfectly matched antenna is lost to re-radiation?
So by astute choice of feedline length we can choose
constructive interference or destructive interference
in the re-radiated signals? :-)

Yes, but the question from quantum physics is: Is the RF dead
or alive before you open the box?

Reg, G4FGQ wrote:
"Well, it sure makes a change from quoting or mis-quoting Terman."

Yes, it may be fun to condemn flawed information. There is not much amiss or paradoxical in Terman`s encyclopedic 1955 "Electronic and Radio Engineering". I found a typo, I think, on page 817:

"It is apparent from these considerations that the lower frequencies (535 to 1605 Mc), the highest antennas that it is practical to use at the transmitter and receiver are such that the direct propagation of vertically polarized energy between the transmitting and receiving antennas (i.e. not including ionospheric propagation) is necessarily by the ground wave."

Frequencies of 535 to 1605 MHz do not propagate by ground wave. Frequencies of 535 to 16o5 KHz do. Therefore I think the "Mc" was a typo. I am a lousy proofreader, but I`ve read Terman for decades and found only a single error.

Best regards, Richard Harrison, KB5WZI

Cecil Moore wrote:
> I knew I was confused about what you were trying to do.

John, I just realized what is wrong with gamma feeding a
1/2WL vertical at the base. The currents in each side of
the gamma feed section are pretty much out-of-phase so
they don't radiate (much). Conclusion: Gamma feeding a
1/2WL antenna at the base results in a field strength
comparable to a 1/4WL vertical and the minuscule amount
of gain is not worth the effort. Antenna gurus probably
already knew that but it just dawned on my concrete brain.

In much the same way a Zepp or a J-Pole is not a 3/4WL
radiator even though they are 3/4WL long, a gamma match
on a base-fed 1/2WL vertical doesn't yield a 1/2WL
electrical radiator. For this reason, the length of a
gamma match should be considerably less than a wavelength.
A good rule of thumb is probably in the ballpark of less
than ~6% of a wavelength. Your idea seems to require about
16% of a wavelength.

Moral: Physical length and RF electrical length are not
always the same.

What you are trying to do apparently requires a J-Pole
or Zepp approach, i.e. a physical 3/4WL antenna.

Cecil:

One element I do not understand in EZNEC is: say I end up with 225 ohms inductive reactance in the gamma rod(just an example figure, use any you please), how do I inform EZNEC I am inserting a 225 ohm capactive reactance, at the feedpoint to offset it?
Or, I am all wet in considering this?

Regards,
John

Cecil:
Yes Cecil, there is wisdom in your words...
However, as I pointed out, I am now focusing on "received signal", its' quality and strength.
After having given it some thought, that is what is most important. In an grave emergency I have the ability to bring multiple kilowatts on line (yes, I have the generator to support it.) What I can't do is guarantee that for the fellow at the other end of the contact. So, I am focusing my attention towards his/her benefit--in the refinement of my ability to pull sub-nano-watts from the ether...
EZNEC and all other calculations are great, I appreciate what can get me to ballpark figures with matching, lengths, spacings, predictions, etc.
But, in the end, the humble s-meter on a known transceiver, compared against know signals and similar conditions will be my final guide and the determining factor.
To all which point out I "may only be"/am duplicating past work, while making futile attempts, or expelling great amounts of energy in this pursuit, I say: "It keeps me out of the bars and away from the wild women!" (saves on my Jim Beam/Viagra bill too!)

Warmest regards,
John

Henty Kolesnik wrote:
"How about a little more explanation on the 50% reradiation?"

The antenna doesn`t care where the power comes from. It can be from connected drive or induced. Induced power has two loads, radiation resistance and connected load (receiver input). If they are matched (equal), 50% is absorbed in each.

If they are mismatched, paximum power transfer can`t occur. A higher percentage of the available energy will be rejected or reradiated because the receiver input is nearer to an open circuit (rejection) or a short circuit (reradiation) than it is when it is matched to the antenna`s radiation resistance.

Best regards, Richard Harrison, KBWZI

Cecil, W5DXP wrote:
"If we simply amplify the receiver voltage through a near infinite impedance FET with virtually no load on the signal, do we get the signal information?"

Not as much as possible.

Just as the reactance must be tuned out of an antenna to receive maximum available power, to get maximum received carrier power, the resistance of the load in the antenna must be reduced to only that matcing the radiation resistance. Walter Maxwell, W2DU has had it right all along. Maximum power transfer requires a conjugate match.

Best regards, Richard Harrison, KB5WZI

OK....I think I uderstand the transmitter side, perhaps a little better. If a 50 ohm transmitter is matched to a 50 ohm antenna there is no reflection and all the power is radiated. If the antenna is not 50 ohms then there is reflected power from the antenna to the transmitter and since the transmitter cannot absorb power it reflects it to the antenna ad infinitum. I also know that electric power generating station don't like a match because a 50/50 deal is not good for profits. I understand the transmitter and power generator however I'm having trouble getting my mind around whats happening with the receiver and antenna. Can it be put another way so I can try to understand it?
tnx

I happend across this just the other day. On page 1426, "Physics:
Volume Two Electricity, Magnetism, and Light", Ronald Blum/Duane E.
Roller it reads "Note that the optimum power transfer occurs when p=0,
R=Z0, and t=1. [p and t are reflection and transmission coefficients]
In general, for lossy lines, this takes place when the load impedance in
the complex conjugate of the characteristic impedance, just as with
lumped circuits."

Seems to be the only way for p = (R-Z0)/(R+Z0) = 0 and
t = 2R/R+Z0 = 1 to hold true for any Z0.

Roy, W7EL wrote:
"Who cares that you have a 50 dB null in one particular very narrow direction, if a few degrees away the response is 40 or 50 dB greater."

This is an example of Roy`s earlier post which noted differences between amateur requirements and commercial requirements. Roy is right. There are real differences.

Commercial licensees operate on assigned frequencies and enjoy some protection from interference on their assignments. A broadcaster may as a condition of his license be required to have a null in one or more azimuths in his pattern to protect another broadcaster who was there first. In this broadcaster`s case, he is interested in the narrow null and may very well expect and hope his signal a few dgrees away is 40 or 50 dB greater.

Hmmmm, your analysis is interesting. The gamma looks very much like an
"auto-transformer" to me--the gama-rod like a variable primary, the
secondary being the complete driven element.
I suspected the action would be identical to the auto-transformer--where ALL
the turns in the secondary deliver power to the load....

Hi Hank,

This again points out the fallacy of treating different matches as
having equal outcomes.

A simple, intuitive test of your statement about would ask the
question:
"Who needs a tuner for mismatches then?"

No doubt the thread will enlarge with discourse on the theory of
Thevenin (Norton by implication), Conjugation, Efficiency, Max
available power, Max power transfer, and any number of other mantras
dear to the heart. And yet none of them will explain that if we have:
>transmitter cannot absorb power it reflects it to the antenna ad infinitum.
"Who needs a tuner for mismatches then?"

Saving a few hundred rounds of such non-answers, and suspecting if I
held feet to the fire, the discussion would then turn to answering
"Who needs a tuner for mismatches then?"
in terms of psychology:
"A tuner makes the transmitter happy."

A such, it reduces to the economy of time. If you are in this hobby
long enough, the investment in a tuner will yield that same level of
transmitter happiness at a lesser expense than would monthly visits to
the pharmacist for Prozac.

Source record: 79501

have you tried this???
http://www.google.com/search?hl=en&q=gamma+match+yagi+design
lots of sources for design info, some software, plenty of pointers.
basically once you have a yagi and decide to feed it with a gamma match you
have the following variables you can work with (assuming you aren't going
to change the diameter of the driven element)...
1. rod diameter
2. rod to driven element spacing
3. location of shorting strap
4. value of capacitance
5. length of driven element(don't forget this, it is very important part of
adjustment!)

now basically you pick a rod diameter, usually 1/3 to 1/2 the diameter of
the driven element, but basically whatever you happen to have handy that is
a reasonable length. then make a few brackets to space it a couple inches
from the driven element, from about 1" on 2m to maybe 4-5" on 20m. so that
fixes 1 and 2.. then you have 3 other variables you can adjust to get the
match you want. if you can't find a good match after systematically running
through the other 3 then try changing the spacing a bit and start again...
but i've always been able to get a decent match by just picking what was
handy for tubing and spacers.

and don't overlook a T match. if you use a 1/2 wave phasing line and the
right diameters and spacing you can get away without a capacitor. this
makes for a fully dc grounded plumbers delight construction that is very
rugged and simple to adjust. this was how all the old telrex monobanders
were fed.

342. Re: VF, low-loss line, high-impedence line - relationship

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-07 00:05:06 UTC
From: K7ITM <k7itm@aol.com>
Message-ID: <1112832306.267536.175570@o13g2000cwo.googlegroups.com>
Source record: 79507

By way of agreeing with what Reg posted about capacitance indirectly adding to the loss, consider that for any TEM line (twin-lead and coax being two examples), the impedance, Zo, is sqrt(L/C), and the propagation delay, tau, is sqrt(LC) [neglecting the very small contribution of R and G for practical lines at HF and above]. From these two, you can see that C=tau/Zo. If the velocity factor is unity, then tau for a foot of line is one foot divided by the speed of light, about 1.017 nanoseconds. If Zo is 50 ohms, then C for that line would be 20.33pF/foot. If you have line which you know to be 50 ohms and 31.0pF/foot, then you know the v.f. is 20.33/31.0 = 0.656, and by my other recent posting in this thread, you know that its attenuation will be about 1/0.656 = 1.52 times as many dB/unit length as the same line with air dielectric (which would be 50 ohms times 1.52 = 76 ohms).

(The interrelation of tau, Z, C, L, line physical length and velocity factor suggests that you can determine Z, for example, by measuring C and v.f. accurately. Some line configurations let you accurately measure conductor diameters as well. You end up with lots of ways to determine a set of line parameters.)

But note that a 50 ohm air dielectric coax using the same outer conductor diameter would have a larger inner conductor, but MORE loss than the 76 ohm air dielectric line because of the higher capacitance. Quantitatively, it will have about 1.1 times the dB/unit length loss compared with the 76 ohm line...so the difference in loss between air inslated 50 ohm line and solid polyethylene dielectric 50 ohm line (same OD) will be a ratio of 1.1:1.52, or 1:1.38. Going from 50 ohm line insulated with solid pe to 50 ohm line of the same OD with air insulation will cut the dB loss by about 27%. Going from solid to foamed pe will get you about half that much. There's a bigger effect going from a solid pe 75 ohm line to an air dielectric 75 ohm line, cutting the dB loss by over 42% (assuming I didn't screw up the calcs too badly).

Cheers,
Tom

Cecil:

Here is the crux of my fruitless attempts to use EZNEC...
With EZNEC, when I plug in the value of my gamma rod and -jxr, along with all other elements, EZNEC spits out an error! (something about too short a loop seems to bother EZNEC, but this short loop IS working!)
However, I am looking at a REAL and functional antenna which appears to be well matched and receiving well.
So, I end up throwing up my hands and just using the antenna and going about with the "cut-and-try" method! (probably just my inability to use the app)

Regards,
John

This thread has provided many laughs. I`m sorry to to insert a serious, on my part, posting, but it may bring a chuckle too.

Terman writes on page 874 of his 1955 edition:
"The spacing of the individual antennas in a broadside array has only a secondary effect upon the directional characteristics of the array provided the spacing is not too great. Thus, when the individual antennas are isotropic radiators, vbarying the spacing from very small values up to 3 lambda/4 affects only the minor lobe structure, as shown in Fig. 23-11 b."

Best regards, Richard Harrison, KB5WZI

Congratulationns!

In a previous posting, I quoted Dr. Arnold King who wrote prior to 1945:
"The accurate calculation of the (antenna) input impedance at AB of the modified antenna as a function of the impedance (presented to the matching section) and the (wire) lengths AC and BD has not been accomplished."

If it were easy to calculate, they would have done it. They had excellent marhematicians prior to 1945, too. The implication is that you find the match by trial. John proved he could do it.

Best regards, Richard Harrison, KB5WZI

Conductors don't "hinder" the traveling of energy. Energy travels just as well along close spaced conductors as it does along wide spaced ones. In fact, loss due to radiation is greater with wider spacing than narrow (although it's still negligible with the lines typically used).

> It helps if the balanced line is designed to be close to the
> theoretical impedance of free space.

Please explain in what way it "helps". No equation, formula or theoretical treatment I'm aware of shows any advantage, change, or anomaly in tranmission line behavior at a value equal to or near the characteristic impedance of free space. (As has been pointed out many times before in this newsgroup, the impedance of free space is the ratio of E/H fields in a plane wave; the impedance of a transmission line is the ratio of voltage to current of a traveling wave. Although they have the same unit of measure, they're different things -- like foot-pounds of work and foot-pounds of torque.)

The price to pay is that it is
> more susceptible to the environment.

Do you mean that lines of approximately 377 ohms impedance are more susceptible to the environment than 200 or 600 ohm lines? In what ways? Why?

The loss in coax is a trade off
> to achieve stability.

Coax is more stable than open wire line? Does open wire line drift in some way?

==========

In fact, the field radiated from correctly balanced twin or open-wire lines is directly proportional to wire spacing.

Radiation resistance is the same as a monopole of the same length as the wire spacing in terms of wavelength. Rr even at VHF is quite small.

Radiation is off the ends - i.e., in the same direction as the line.

Polarisation is in the same direction as the wires are spaced.

And, believe it or not, all is independent of the length of the line.

Use the "Loads" feature to install a lumped point load of
any Q. For instance, a coil might be 10 + j300 ohms or
a cap might be 2 - j500 ohms. The position of a load
is similar to positioning a source.

But the information in a received signal can be had while
consuming very little of the received signal's power. For
instance, ten feet of wire into my IC-756PRO results in
perfect reception of Neal Boortz on WTAW on 1620 kHz.

Or maybe not. EZNEC apparently won't properly model
the Lattin antenna. www.g3ycc.karoo.net/lattin.htm

Somewhere I have a .ez file that shows 20 dBi omni-
directional gain from an inverted-L antenna. Now that's
what you need. :-)

And you taught me something today. I didn't know one
can attach .ez files to a newsgroup posting.

RL> Do you mean that lines of approximately 377 ohms impedance are more
RL> susceptible to the environment than 200 or 600 ohm lines? In what
RL> ways? Why?

Since a portion of the EM field in open wire line is free to travel
outside the conductor into the environment then we may safely assume
there is an exchange between the environment and the conductor. If the
impedance of each is approximately the same then there is less loss in
the interface between the two. It has to do with the reflective
coefficient where the energy is returned. You will note 300 ohm open
line has less loss than 100 ohm open line.

RL> The loss in coax is a trade off
> to achieve stability.

RL> Coax is more stable than open wire line? Does open wire line drift in
RL> some way?

It is susceptible to ambient humidity and proximity to conductive
objects (birds, snow, rfi). That is a source of drift in practical
terms.

A small loop antenna with a perimeter only a small fraction of a wavelength has almost uniform current throughout. Its impedance is an inductive reactance in series with a resistance. The U.S. Bureau of Standards published inductance formulas for single-turn and several-turn loops in Bulletin 74. Results can`t take into account loss from radiation so they are approximate.

Arnold King gives an approximate formula for the radiation resistance of a small one-turn loop in "Transmission Lines, Antennas, and Wave Guides":
Re = 20(Beta)to the 4th power times A squared
Beta=2pi/lambda
A=area enclosed by the loop.

>. . .

I took a look at it, and sure enough, it can't. The antenna is constructed from tubular 300 ohm twinlead, and EZNEC has no way to account for the dielectric between conductors. In that antenna, it looks like the velocity factor of the differential mode field between conductors would be important to its operation, and without the ability to model the dielectric between conductors, EZNEC wouldn't get the velocity factor right.

When I see a claim that EZNEC can't model a particular antenna, I often find that the reason for the claim is that the antenna's inventor or seller has dreamed up some magical property to explain the impossibly good performance he's claiming for the antenna. EZNEC models the antenna just fine, it just doesn't model the magical property and validate the claims -- that is, it shows how the antenna really works, not how the huckster claims it works. But there are, certainly, some kinds of antennas which it really can't model properly for one reason or another. The Lattin antenna is one of those.

Another question...

We have underground utilities in this neighborhood. The box on the side of my house where the utility feed arrives has an approximately 1ft section buried. There's actually a grade line marked on the side of the box which I presume is a "do not exceed line. The service no doubt enters through the bottom of this box.

I've dug carefully on one side of the box and so far haven't found a ground rod. Before I continue digging I have a question about the ground rod location.

Is it possible/typical that the contractor would put the ground rod underneath the service entrance box in cases like these? If so it would probably be pretty difficult to get to it.

Would driving another rod within a foot of the service panel be adequate? (of course taking care not to penetrate the AC mains!)

I noticed the phone guy just put a hose clamp on the big metal compression nut that has one side of the mains leading into the house and put his ground under that. This is on the outside of the service entrance box outside the house.

Would grounding through a similar compression bond to the box be a reasonable alternative?

tnx

Hi Jim,

The buried conduit casing of the AC mains entrance to your meter is most likely NOT your house ground. The main AC breaker panel for your home, whether that be in a garage or wherever (surely close to the meter though) is where the house AC neutral wiring and house AC ground wiring all meets at one bonding location. THAT is the source of the single point ground conductor, which leaves your panel and finds the nearest approved earthing connection. You may have to get under your house to see where that green bonding jumper drops down from the panel, and penetrates the outside wall, then connects via a bronze ground rod clamp to the home's single point ground rod. Telephone and cable and all radio shield grounds MUST BOND to this ground rod. It is probably just inches beneath finished grade, and

within a foot or so of your foundation wall, right outside the breaker panel.

In the unlikely event that your builder actually used the aluminum casing of buried conduit for his AC mains ground connection, then the telephone company was proper in bonding to the same place. But if you have a buried ground rod as 99% of residences do, then that is the ONLY place that all utilities must ground to.

The reason it would be unlikely to have the conduit as a earthing ground connection? Because the utility should inspect for a contractor installed ground rod before they hook up. Using their buried conduit, while possibly legal, would be unusual at best.

Hope this helps,

Jack

Hi Roy,

Having model dozens of variations of this antenna, as well as what was described in the patent - I cannot think of one reason why it should work except through haphazard luck. Certainly the offered "theories" are no more credible than those for other antennas that defy modeling such as the single or double bazooka, the eh, the cfa.

This antenna has many reports of its confounding expectation and then in the same breath those who are confounded expressing their sincere belief it works. It's one of those situations where the builder can't get it to sing, but has a brother-in-law who knows this fellow who lives next door to one who can, but who took it down ten years ago because it was so hard to tune.

Perhaps you could widen your customer base if you added a "belief scale" to the available control settings for EZNEC. It could range from "agnostic" to "I believe in miracles."

Cec, you took the bait.

So just exercise a teeny bit of your imagination.

Suppose you have a generator directly connected to a load resistance
without any line in between.

Let the generator and load terminals both be spaced apart by the same
distance as the conductors of the non-existent line.

The load carries a current along a length equal to the spacing between
its terminals.

The load, by virtue of its length, possesses radiation resistance.

And so radiation occurs with zero line length.

Even a CB-er can understand the obvious.

Can you calculate radiating efficiency?

Cecil, W5DXP wrote:
"But the information in a received signal can be had while consuming very little of the received signal`s power."

Very true, but with AM, or even with weak FM signals, below the "FM Improvement Threshold", the modulation recovered varies directly with the strength of the received carrier

Receiver alignment instructions often advise using a modulated signal from the generator which is weak to ensure operating in a region where there is a dB to dB relationship between the received carrier strength and the demodulated signal strength.

You can probably hear Neal Boortz on Aggieland`s 1620 kHz without a receiver.

Best regards, Richard Harrison, KB5WZI

Hi Jack

Well I moved some stuff around in the basement and found the house ground. It actually protrudes out of the concrete floor directly below the two breaker panels. Each panel has what appears to be #4 solid copper coming down to bronze clamps on this rod.

There's no ground outside at all which is why the Verizon guy chose to ground to the Thomas and Betts meter cabinet that I mentioned which is 4ftx6"x15" or so and partially buried. Here in MD they just do direct burial rather than use a conduit. The entry to the house panels from the meter box is just via heavy cable, no conduit there either. The Comcast guy just put a ground on the splitter and ran it a foot or so to the closest circuit breaker panel.

So should I just drive one more rod pretty close to the box to finish the daisy chain close, then go inside and bond to the single point there? Seems crazy to take this inside... I'll have to drill a hole through the sill plate on an angle then feed the wire up from my proposed exterior ground rod, through the sill plate, then down the inside of the concrete basement wall to where the other two grounds are attached to the ground post.

tnx
jtm

There are warnings in EZNEC about segments not lining up
between close spaced wires. My 29 dBi omnidirectional
antenna is an example of what happens when one ignores
the segment alignment between closely spaced segments.

I have modified your segmentation to try to follow the
EZNEC guidelines and that file is attached. There is
quite a change in the results. The feedpoint impedance
went from 2.787+j15.47 to 0.7587+j22.69, the gain went
from 7.23 dBi to 3.16 dBi, and the TOA went from 6 deg
to 9 deg. I standardized on one foot per segment.

I don't really understand what you are trying to do and
am just the messenger.

Did you remember to attach the file? I don't see it, but would love to study your changes...
At ~2.7 ohms I can use a 1:16 balun (reversed direction from conventional use) to mate the antenna with 50 ohms, and get an acceptable SWR...
Cecil, try to hear this in a positive manner: If I must conform to EZNEC, then any creativity must be abandoned... If I conform to all the rules of the past and the "Absolute Truths" encompassed by any application--how could I ever hope for a new discovery of geometry or configuration, or the possible use of un-used manipulations of existing rules?
If one travels the same road, takes the same plane, rides the same rail, boards the same boat, walks the same path--he sees only the same sights, that which is common place.... even futile paths invoke my curriosity--as just a change of scenery can be enjoyed many times.
If that argument is carried out to its nth degree, only one question would remain, "Why should I bother with any of this?", it would be quite easy for a programmer to create a program which quizzes you on ant type (monopole, dipole, yagi, 1/2 wave, 1/4 wave, center loaded, bottom loaded, etc, etc), the freq etc... then constructs the antenna for you. Including suggesting height, mounting brackets and a host of other varibles and conditions that tasks the mind to consider... In other words, once I give control and authority to EZNEC, why should it not "do it all?"
But then, even if it did, I would still dilly around with these copper, aluminum and stainless bits and pieces. <grin>
You have talked me back into abandoning EZNEC....

Regards,
John

If the conductors are perfectly conducting, no part of the field at all exists within the conductor. With good conductors like copper and at HF and above, there's very little penetration of the conductor by the fields, either electric or magnetic. As far as an "exchange" goes, it sounds like you're trying to describe radiation. If not, what's the phenomenon you're referring to?

> If the
> impedance of each is approximately the same then there is less loss in
> the interface between the two.

No, that's not true. First of all, a mismatch doesn't cause loss. Secondly, as I explained in my last posting, the characteristic impedance of a transmission line isn't the same thing as the characteristic impedance of free space. If you were to construct a transmission line with 377 ohms characteristic impedance (numerically the same as the characteristic impedance of free space), the ratio of E/H fields between the conductors probably won't be anywhere near 377 ohms, as it is in a plane wave propagating without wires.

It has to do with the reflective
> coefficient where the energy is returned.

Well, no. There isn't a bundle of energy trying to escape the line and bouncing off the air, or bouncing off the air as it travels along the line, or bouncing off the conductors into the air. So reflection coefficient isn't applicable here.

You will note 300 ohm open
> line has less loss than 100 ohm open line.

Yes, and 600 ohm line has less loss than 377 ohm line. You'll have to find a way to fit this into your theory if you want to pursue it.

> RL> The loss in coax is a trade off

> objects (birds, snow, rfi). That is a source of drift in practical
> terms.

Thanks for the clarification. Because the differential fields are completely confined within a coaxial cable, they are indeed more immune to external influences.

I'm afraid that the conclusions you've reached about loss and characteristic impedance are based on a poor understanding of fundamental transmission line operation. The result is some conclusions that are, and are well known to be, untrue.

If you really feel that you have a viable theory, you should be able to provide some equations and formulas to quantify the extra loss you're talking about. The existing theory, formulas and equations, in daily use for over a hundred years, have been shown countless times to accurately predict transmission line loss, and they don't include the phenomena you're describing. So although I think it's highly doubtful that your formulations will prove more accurate, if you post them they can pretty easily be tested by actual cable measurement.

Sterba and Feldman in "Transmission Lines for Short-Wave Radio
Systems", Proceedings of the IRE, Volume 20, No 7., July, 1932 give a
formula for the radiated power in a balanced line.

The line length *is* a factor, however, they give a simplified
approximation for the case of a length more than 20 times the line
spacing and the line spacing less than 1/10 lambda.

P/I^2 = 160 * (pi * D / lambda)^2

where:

P is in watts

I is the RMS current in a matched line

D / lambda is the wire spacing in wavelengths

I don't see line length in the formula.

What do they say about line lengths less than 20 times wire spacing
for small spacings?

I'm looking for any suggestions on what type of H.F mobile antenna to purchase. I want to install this Antenna on a 97 Chevy S-10 Pick-up. I would like it to cover 80meters through 10 meters. The mount system is what I am really interested in. Not sure which way to go on this, never have been mobile with HF before. The pickup is a extended cab by the way. Any suggestions would be appreciated.

What about your cargo box? Do you have one, is it metal, and is it
semi-permanently mounted - i.e., is it bolted to something solid? Do you
have any big objection to mounting an antenna on the cargo box? I'm a big
fan of the Hustler, but it does mean changing traps for each band.

The purpose of the Deep South 2 Meter SSB Net is to promote 2 meter SSB activity in the region by bringing 2 meter SSB enthusiasts together. It also serves as a vehicle for arranging skeds, obtaining new grid squares and new states for it's participants. The net meets 7 nights a week on 144.240 MHz USB at 8:30pm CST and is open to all. A swap meet follows the net every evening. Net is called by Charlie,AD5TH from EM52kn. The Homepage for the Deep South 2 Meter SSB Net is www.deepsouthnet.net An attractive certificate is available for free to those with at least 100 successful check-ins. For more info contact Charlie at ad5th@direcway.com

Hi folks, I'm in the process of building myself a screwdriver antenna for my truck. Being the vain sort, I'd like it to end up being black as that matches nicely with the other bitties sticking out of the vehicle.

Q.- Does anodyzing negatively impact aluminum's ability to efficiently radiate? I seem to recall reading somewheres that anodyzing leaves a non-conductive surface, but on the other hand aluminum oxide ain't supposed to be that great a conductor either & that whats on the surface of any piece of aluminum thats seen air for more than a few minutes.

Enquiring Minds want To Know-

Howard.

378. Single-conductor transmission line?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-08 01:37:22 UTC
From: Hal Rosser <hmrosser@bellsouth.net>
Message-ID: <o9l5e.34469$f%4.16353@bignews1.bellsouth.net>
Source record: 79440

I recall reading about an impedence matching technique where the conductors of, say a coax segment, would be spaced slowly more and more apart (like the braid becoming larger like the shape of a funnel) and extending until only one conductor (the center conductor) is required for transmission. A similar setup at the other end of the run would transform the impedence back to usable levels.
The drawings in the article portrayed the transformation as appearing like a funnel flaring out slowly with the center conductor eventually the only conductor - then the same setup at the other end.
The idea of a single-conductor transmission line makes it an inviting idea, but physically building the impedence matching sections on the ends look like a real challenge.

The radiating surface don't care. Just make sure all mechanical contacts which need to conduct penetrate the anodizing.
Like where the coax connects, or where the coil is connected.

I think the screwdriver antenna would be a decent choice, but at hf, you'll
want to get to a base station asap, no matter what mobile antyenna you end
up with.

Richard Fry wrote:
"But--isn`t program recovered in FM systems a question of carrier deviation only?"

Certainly so when the signal is ample. That`s about the biggest advantages of FM and essential to the success of repeaters.

I`ve found and aligned countless FM microwave paths. I always started by transmitting signal from an audio generator directly on the baseband at one end of the path. On the receive end of the path the tone comes out of the order-wire loudspeaker when the dishes are aligned well enough to find some. It does not go from none to some instataneoisly as if keyed on. It fades in. Initially, the signal is too weak to register any increase in limiter current. The tone gets louder when the dishes come on path, though no one has changed the deviation. You just have more signal and it behaves much as it would were it an AM signal while it is weak. When you can hear the tone well you begin to have limiter current increase so I usually attached an external limiter meter and either sent it or carried it up the tower to refine the dish position for maximum limiter current.

Driving across the country listening to FM on the fringes one may notice background noise, scratchy audio, sudden changes to the station being received, and a gradual change in the audio level from the loudspeaker. It is not nearly the change one notices in audio versus distance in AM reception, but I notice it and adjust my volume control accordingly. More things happen at the FM improvement threshold than appearance of noise sputter.

Best regards, Richard Harrison, KB5WZI

If money is not a problem, I would install a screwdriver antenna. I have been a County Hunter since the mid 80s and I have used every type mobile antenna there is I believe from the Hamsticks, the Spider, Hustlers and the famous Texas Bug Catcher. The Screwdriver is the best thing that happened for me, convienient and very effective. For me the bug catcher was the best if I could lleave it on one frequency. With all the other antennas (except for the spider) you had to stop and get out of the car to change bands or make big freq. jumps. The spider had preset stingers for each band but this antenna was even worse than than the outbacker. I couldn't get rid of either of them fast enough.
Just do a search for screwdriver antennas and you will have a field of antnnas and installations. Truck installs are much easier than cars.

I mounted my S-10 mobile antennas in the trailer hitch
hole. I replaced my tail gate with a non conducting
net across the back. Worked well except for the ABS
noise from the S-10 braking system which drove me nuts.

A single-wire transmission line has a Z0 of a few
hundred ohms. A transformer at each end is all you
need for impedance matching. The single-wire section
will radiate but it's surprising to me how much power
can be delivered to a load at the end of the wire.

My Electronics Equations Handbook give the Z0 of a
single-wire transmission line as 138*log(4D/d) where
'D' is the distance above ground and 'd' is the
diameter of the wire. A 0.1" dia. line 30 ft. in
the air has a Z0 of 574 ohms.

SIGNALS FADING FROM SHORTWAVE BANDS

Mysterious weakening of frequencies puzzles scientists

Columbia, MD- Officials at the Federal Communications Commission (FCC) have observed a steady deterioration in shortwave signals over the past decade, and have kept the findings secret while they scramble to find a cause, a government insider told a gathering of the American Shortwave Listeners' Society Tuesday.

Measurements taken at various FCC monitoring stations show that signals are degraded compared to ten or fifteen years ago, but only on certain frequencies. The variation cannot be attributed to the solar cycle, which causes signals in the shortwave bands to rise and fall every 11 years or so.

"What we are seeing is very, very strange, indeed," said a scientist with the National Institute of Standards and Technology, which obtained the results of a study conducted by FCC between 1989 and 2004. "It seems that only certain very specific frequencies are affected, while others are completely immune to the effect," she said.

Robin Ferguson, a senior member of the technical staff at NIST and congressional lobbyist, cited three specific channels that are especially disturbed but without a plausible explanation for the malady that affects only these three and not the frequencies immediately above nor below them. At the annual convention of the shortwave listeners, she described the serious degradation that is eroding the ability of these shortwave signals to carry communications.

"For some reason, we are measuring a definite 14 to 20 decibel drop in signal strength as we sweep across 7.258, 10.000, and 14.230 Megahertz, just to name a few," she announced. "It is almost as though those frequencies were overused, that they are somehow being worn out from almost constant use by relatively high-powered transmitters and can't support these signals-any signals-anymore. I know this sounds crazy, but the measurements don't lie," she stated.

Attempting to explain the mystery in terms understandable by the layman, Ferguson likened the effect to the deterioration of the ozone layer, "Except it's the ionosphere that's involved here, but the real puzzle is why only these frequencies? It's like the ionosphere knows what frequency you're on, and selectively fades you out."

Until more data are collected, the condition appears permanent.

Ms. Ferguson revealed several more frequencies that have fallen prey to this mysterious radio disease as members of the audience made careful note of

them. "Take a listen also on 3.885, 15.000, and 27.495 Megahertz, and you may be surprised at what you hear-or should I say don't hear," she said.

She pointed to a section of the study where worldwide communications were being conducted on 14.220 Megahertz, but the same signals, when they moved to 14.230 Megahertz, a scant 10 kilohertz higher, were too weak to hear and covered by noise. The effect has never before been observed.

Both 10 and 15 Megahertz are frequencies used by WWV, NIST's time and frequency radio station in Fort Collins, Colorado, which operates 24 hours a day and lends credence to the theory that the frequencies are simply wearing out from overuse. The other frequencies have no specific user but are part of the amateur radio service's allocations. They are used heavily by ham radio operators to talk to their friends on the air.

"The question that is really concerning us is whether there are other frequencies about to go south, and whether we can do anything to stop it from happening," Ferguson said. She added that a worldwide moratorium has been proposed while tests continue to test the 'overuse' theory, but she said opposition would be stiff from many shortwave users who would be affected, especially hams who use these frequencies. She stated, "I understand it would be somewhat of a hard sell to ask them not to get on the air, but after all, they are just hobbyists and I believe the federal government could invoke the authority to give us the quiet bands we need to make our measurements." In one scenario being considered, 'quiet hours' would be imposed on hams for a limited amount of time each day.

Ferguson pledged continuing efforts to identify a cause, but warned that budget cuts at FCC might hamper further research.

Good job scoping out what you have, Jim. It is unfortunately, non-conformant by your description. Utility service entrances are required to be single point grounded at one entry point. Bonding through basement walls will never meet that requirement, besides being difficult to accomplish.

The potential between your Verizon lines and Electric lines could be huge, should the nearby utility pole, a tree in your yard, etc be struck. The phone issue may never be a problem unless...you use phone-patch equipment connected to a radio.

You previously asked if it is allright to improve the AC mains ground rod (when you thought you had one outside). The answer is yes, and most as installed by the building contractor are barely sufficient for handling surge voltages that nearby lightning can send to the meter. Adding a second and third ground rod (in a "Y" formation for instance) greatly improves the protection from utility high voltage damage to your home, providing you have good surge protection installed. Sans surge protection? Don't bother with more ground rods.

In your case though, you probably have an excellent grounding electrode under the house. You do realize that the finished grade outside is probably as much as 10,000v "above ground" from that under-basement electrode! Too bad Verizon didn't see fit to make their box ground at the same place. I would ask Verizon what to do, get a grounding technician to come out to your place and explain to him that you have communications equipment connected and expect a code-installation of all utilities before you can complete lightning protection systems. If he demonstrates to your satisfaction that it DOES meet code, please sketch (paint program, or photos scanned, etc) what you have and send it. I will be happy to get a telco communications engineer to comment (and it won't be Verizon). It may be that the electrical code and telco standards *do not protect you* in your individual circumstances.

Meanwhile, you can make a bond between your AC panel ground rod and the station single point ground, as most of us are unfortunately situated far apart when ideally they would be next to each other. That bonding connector can be insulated wire through interior walls, utility chases, under floors, etc. Preferably use #6 wire minimum. It HAS to be much lower impedance that the home's AC outlet grounding wires, how much lower is up to your individual circumstances. I just replaced #4 copper with 13" wide 20 gage copper sheeting, because I had over 50' of separation between station ground and AC mains ground. That's an awful potential, and begs high voltage felt at the station ground from a nearby strike, to blast out the back of the radios and into the power grid. Surge protection alone cannot save you from ground potential rise, but a bond from station ground to AC ground that is much lower impedance than the house wiring will MINIMIZE the effect on your equipment, and all home appliances. Richard Harrison in this group had a much better solution for my type of problem, and that was to route ALL antenna feedlines to the AC Mains ground point BEFORE entering the home. Unfortunately that would have been a design issue when I started my station, and so I used the next best alternative, the best bonding possible between the two.

I suggest proceeding with that effort and shield grounding, etc, until an expert from the telco and/or electric company can visit and review your situation.

Best regards,
Jack

That's the name. It was once promoted as an alternative to large waveguide for UHF transmission, until low-loss coax came on the scene.

Unfortunately G-line has a number of practical problems, all involved with keeping the propagating EM field attached to the single wire, and preventing it from radiating like a long-wire antenna. If the line radiates, that energy fails to reach its destination at the other end - which of course means loss.

I don't understand the detailed EM physics, but G-line does not use the same TEM mode as coax or parallel line. Basically, Nature never intended an EM field to propagate along a single wire, so it's always trying to fall off and radiate. To keep the field attached, the wire needs a fairly thick, low-loss dielectric covering (bare wire won't work). The line also needs to be straight and uninterrupted, so practical installation is extremely critical. G-line is always trying to become a long-wire antenna. Make any mistakes, and that's exactly what you'll get.

Coax of course is the complete opposite, so Heliax and other forms of low-loss hardline have wiped G-line off the map. For many years it has been nothing more than a technological curiosity.

But now it seems to have made a reappearance as a carrier for BPL. Yet the same basic problem is still there: in any practical installation, G-line is *always* trying to become a radiating long-wire antenna.

Most FM broadcast stations in the US use some form of dual polarization, which they think of as "circular" but usually is not due to differing H&V pattern distortions from the mounting structure supporting their antennas. Paper 6 at http://rfry.org discusses this in the form of NEC-2 studies.

In some cases, several FM stations all use a common antenna at a master FM site. An array of "cavity-backed radiators"* used in these cases can provide a c-pol axial ratio of 2dB or less for all polarization planes. Antennas of this design are used as master FM antennas in Houston, Dallas and St Louis, where they radiate approximately eight FM stations of 100kW ERP each. Sears Tower in Chicago has a number of them installed in a vertical stack for use by individual FM stations.

*crossed, wideband dipoles in phase quadrature, installed in a circular, wire mesh cavity about 1/4-wave deep and less than a wavelength in diameter and arrayed in groups of three or four around a triangular or square cross-section tower. Several levels (often 8 or 10) are used to provide elevation gain for the array.

==========

Ian, you are falling into the same sort of trap as old wives who
imagine most radiation comes from the middle 1/3rd of a dipole because
that's where most of the current is.

It is self-misleading to consider the various parts of a radiating
system to be separate components which are capable of radiating
independently of each other. They can't. A system's behaviour must
be treated as a whole.

We have already discussed that the power radiated from a generator +
twin-line + load is a constant and is independent of line length.

Total power radiated is equal to that radiated from a wire having a
length equal to line spacing with a radiation resistance appropriate
to that length. The location of the radiator, insofar as the
far-field is concerned, can be considered to be at the load. The
current which flows in the radiator is the same as that flowing in a
matched load. And the load current is independent of line length.

Mathematically, the only way for the total power radiated to remain
constant and independent of line length is for zero radiation from the
line.

In summary, the system as a whole BEHAVES as if there is NO radiation
from the line itself - only from fictitious very short monopoles (or
dipoles?) at its ends.

Reg, G4FGQ

Ian, G3SEK wrote:
"Now tell us about radiation from the line."

Reg`s problem has a line as long as it is wide. That would make a very small square loop if I read right. The same current flows in all 4 sides.

According to Arnold King:
Beta is a factor = 2 pi/Lambda
Say Lambda=1, then Beta=2pi

Radiation resistance= 20 times Beta to the 4th times A squared

Say the sides of the tiny square loop are 0.01Lambda, then A, the loop`s enclosed area is
0.0001

Radiation resistance =
20 (1555) (10 tp -8th)

=31100 (10 to -8th)
=0.00031 ohm

Radiated power = Isquared (radiation resistance)
Radiated power = negligible

Best regards, Richard Harrison, KB5WZI

Hi Wes,

Could I trouble you for a copy of section IV that continues on beyond
page 1180? I am interested in the discussion relating to Figure 12 so
you can restrict your efforts to that if this section runs on too
long.

Thanks,
Richard, KB7QHC

Actually they can, because that isn't the same as saying...

>A system's behaviour must
>be treated as a whole.
>
That is true, of course. Every component of an antenna (or in this case,
a parallel-wire transmission line) interacts with every other component.
The totality of those interactions is what determines how the RF voltage
and current will distribute themselves along the wires.

But once you know the magnitude and phase of the current in each small
segment of the antenna (which need not depend on theory or modeling - in
principle you could go around and measure it) then you have taken
complete account of the interactions. The radiated field from the whole
antenna is then the sum of the fields from the individual components
radiating independently.

However, we weren't originally talking about that...

>We have already discussed that the power radiated from a generator +
>twin-line + load is a constant and is independent of line length.
>
No, you have only asserted that.

>Total power radiated is equal to that radiated from a wire having a
>length equal to line spacing with a radiation resistance appropriate
>to that length. The location of the radiator, insofar as the
>far-field is concerned, can be considered to be at the load. The

>current which flows in the radiator is the same as that flowing in a
>matched load. And the load current is independent of line length.
>
Only if there are no radiative losses from the line itself - and you
have only asserted that, not proved it.

>Mathematically, the only way for the total power radiated to remain
>constant and independent of line length is for zero radiation from the
>line.
>
Well obviously - but that is a circular argument, based entirely on your
assertion that the power delivered to the load is independent of the
line length.

>In summary, the system as a whole BEHAVES as if there is NO radiation
>from the line itself - only from fictitious very short monopoles (or
>dipoles?) at its ends.

Sorry, but the "behaves as if" argument doesn't wash, because those
short monopoles are real. Since the line spacing is non-zero, those
short transverse sections must always exist, both in practice and in
your circuit model. Each section carries RF current, so it radiates - no
question about that, but it is entirely an end effect. It has nothing
whatever to do with radiation from the main line.

Looking edge-on at the line, we have two conductors carrying equal and
opposite currents, but one is slightly farther away than the other so
their transverse radiated fields do not quite cancel out.

The only question is mathematical: how does the small loss of energy
through radiation translate into a dB/m or dB/wavelength loss along the
transmission line?

It's the CBers. You see, there is a fixed quantity of propagation in the ionosphere and each signal that hits the ionosphere absorbs a bit of that energy. Eventually we reach a point of saturation at which the capability of the ionosphere to support propagation starts to degrade. CBers and their illegal super amps are sucking the ionosphere dry. The only way to reverse the trend is for them to stop transmitting.

The eminent Dr. Larson E. Rapp explained it all in the April 1938 QST.

Ian, G3SEK wrote:
"---how does the small loss of energy through radiation translate into dBm or dB/wavelength loss along a transmission line?"

It is the reverse of a beverage antenna, which is a sort of single-wire transmission line above the earth in its simple configuration. The Beverage is a horizontal wire sensitive to vertically polarized waves. It is working with the wave throughout its travel along its length.

The Beverage is vertically polarized because that is the direction of the electric field between its conductors, the wire and the earth beneath the wire.

The direction of the electric field in a parallel-wire transmission line is from wire to wire. The effective radiator length of this polarization is the line spacing. This is short compared to the length of the transmission line in nearly all cases. The radiation is not emerging from the end of the transmission line. It radiates slightly all along the line as the wave navigates the line, much as the Beverage gathers energy slightly as the wave sweeps along its length.

Best regards, Richard Harrison, KB5WZI

Nope.

Aliens. Stealing our ions for their starships.

I know that some may give me some static about this, or see it as a
negative occurrence. I say we should try to stay positive. In
particle, I look forward to meeting with the aliens. I expect to get a
charge out of that.

No mater what happens, you can be sure we will bounce back.

In a perfect conductor, no. In a real but good conductor like copper,
it's confined to a very thin layer at the surface. Look up "skin effect"
in any electromagnetics or basic text on RF, or google it.

>
>
> RL> First of all, a mismatch doesn't cause loss.

If I connect a 50 ohm source to a one wavelength, 300 ohm transmission
line and connect the other end of that line to a 50 ohm resistor,
there's a 6:1 mismatch at both ends of the line. The power supplied by
the source and the power delivered to the load are exactly the same as
if I had used a 50 ohm line instead. This is, of course, overlooking
resitive loss in the line. If you consider the resistive loss, it can be
greater in one line than the other (the 300 ohm line might be less
lossy), depending on the physical construction of the line.

No loss is caused by the mismatch. No "scattering of energy occurs". All
of the energy from the source arrives at the load, where it was intended.

I'm sorry, I don't understand what you're asking. No RF energy exists in
or travels in a perfect conductor.

> RL> It has to do with the reflective

>
> What makes you so sure?

A basic understanding of electromagnetics derived from an electrical
engineering education, extensive additional reading and study, and about
30 years of engineering design experience including design of microwave
and very high speed time domain circuitry.

I have no idea what makes you think that my modeling or understanding of
transmission lines is limited to lumped constant models -- it's
certainly not true. Indeed, no analogy is perfect, but some are
certainly better than others, and some are demonstrably false. I'm
afraid that some of the ones you've put forth are in the latter category.

==========

Ian, Oh yes they do.

Next to each half wavelength of line there is another half wavelength of line in which the current is in antiphase with it. And so, in the far field, the fields from adjacent half-wavelengths of line cancel each other out.

Now you'll say my logic falls down when the line length is an odd number of half wavelengths. But you must not consider half wavelengths of line to be behaving independently of each other.

427. Help with swr point?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-08 22:36:13 UTC
From: Ken Bessler <kg0wx@NOSPAMyahoo.com>
Message-ID: <xHD5e.3395$up2.2389@okepread01>
Source record: 79392

I just installed a Comet GP-6 and it's VHF low
swr point is 139 mhz. I called Comet and they
said there is no way to tune the antenna. I'd like
to raise the 1:1 SWR point up to 146 mhz. The
closest other antenna is an AEA 6m Halo 5'
below the GP-6. The mast supporting both antennas
is 30' high. I'm using non conductive guy ropes
just below the halo.

I remember there were discussions on this group
about altering "percieved" SWR by changing
feedline length. I'm using 30' of Flexi 4xl coax
from the antenna to my secondary SWR bridge
and a Radio Shack 2' rg58 patch cable from
the bridge to the rig.

I measured a 1:1 at the rig @ 139 mhz and
1.5:1 at the swr bridge (lowest swr seen there)
but the low point on the bridge was 138 mhz.
I was getting a SWR warning on my FT-857D
around 152 mhz and adding a 3' RG-213 patch
between the antenna and SWR bridge fixed that.

So, which way do I go? Shorter or longer?

No, they don't. They cancel only in two directions, directly normal to the plane containing the wires. Radiation occurs in all other directions, because the fields don't add in antiphase. An example of an antenna which uses two closely spaced elements carrying equal out-of-phase currents is the W8JK.

With an SWR greater than 1:1, you cannot use 50 ohm
coax to achieve a match to 50 ohms by varying feedline
length. The target impedance (50 ohms) must lie on
the feedline's SWR circle. With 50 ohm coax, the center
of the SWR circle is the target impedance and cannot be
reached by simply varying the length of the feedline.

You could put a matching network at the base of the
antenna to match it at the desired frequency.

Anonymous quotes:
"---but the real puzzle is why only these frequencies?"

Shortwave propagation has always been highly variable. Selective fading is the rule. So much so, that frequency diversity has proved effective to improve reliability even though 2 or more frequencies must be used for only one channel in but a single direction.

Hit or miss communications makes ionospheric radio obsolete for practical purposes in an age of satellites and optical fiber cables.

For amateurs, hit or miss is part of the fun.

Best regards, Richard Harrison, KB5WZI

Close. It's Goubau, from "Surface Waves and Their Applications to Transmission Lines," J. Appl. Phys., vol. 21, 1950. An interesting variation is described in "Low-Loss RF Transport Over Long Distances", by M. Friedman and Richard F. Fernsler, IEEE Trans. on Microwave Theory and Techniques, Vol. 49, No. 2, Feb. 2001, describing a system the authors describe as "simple, inexpensive, lightweight, and [having] low attenuation". They used a strip of aluminum foil 6 cm wide and 0.02 mm thick with periodic punched holes as the line, strung it around a lab with the strip suspended by threads, and measured low attenuation. How this could translate to a practical outdoor system for "long distance RF transportation" as the authors claim is beyond my feeble imagination.

Darn it Roy, that's your problem... no imagination. These guys
apparently couldn't see the commercial applications either.

They should have written a companion article in Worldradio News about
the super performance they see when using this stuff to feed E-H and
Fractal antennas.

And if they had been really sharp they would have started a company
ahead of time---let's call it "Foilman"---(apologies to Press Jones)
and been ready to peddle this stuff to hams.

A coupla glowing reviews on eham.com and the money would roll in.

Wes

ps. I going to go out and start punching holes in the elements of my
20-meter beam and see what happens.

>So why bother with high priced cable when a piece of clothes hanger
>will do just as well, encantations? I think your are still in April 1
>mode, Mr.Roy. We are way past diatribe here, thank you.

What Roy actually said was:

"If I connect a 50 ohm source to a one wavelength, 300 ohm
transmission line and connect the other end of that line to a 50 ohm
resistor, there's a 6:1 mismatch at both ends of the line. The power
supplied by the source and the power delivered to the load are exactly
the same as if I had used a 50 ohm line instead. This is, of course,
overlooking resitive loss in the line. If you consider the resistive
loss, it can be greater in one line than the other (the 300 ohm line
might be less lossy), depending on the physical construction of the
line."

So you see, our shyster poster left out the part where Roy considers
that resistive loss plays a part, and by inference makes copper wire a
better choice than clothes hangers.

In a Beverage antenna, how much transmit power is lost in the
terminating resistor? We know a Beverage is a very inefficient
transmitting antenna. Could it be because it's a fairly efficient
transmission line? Or is it because of ground losses?

Hello Ken
We beat this one to death some time ago on this group.
A perfectly tuned bazooka (I had to build seven of 'em for 40 meters 'til I
got it nailed.)
exhibits some interesting SWR reduction effects right around resonance,

where the SWR is already so low it doesn't matter,
but any increase in the >1.5:1 SWR bandwidth is due to loss as Walt proved decades ago.
In the mean time you lose 10-20 percent of your signal if you're lucky.
And if the antenna's not perfectly tuned, you lose more than that.
The equivalent circuit is a series-resonant network (the dipole) in parallel with a parallel-resonant network (the stubs).
The (driven) parallel-resonant network oscillates at it's driven frequency when it is driven close to it's resonant frequency, causing the already small reflected power to nearly vanish. Move very far from resonance (where the SWR on a dipole >1.2:1) and the parallel resonant circuit stops oscillating.
I posted quite a bit of data here for bazookas made for 160, 80 and 40.
Don't waste your time, I already wasted mine.
Buy a balun from Walt or make your own and tune your dipole carefully.
There ain't no free lunch.

> transportation" as the authors claim is beyond my feeble imagination.

Heh, heh, maybe they modeled it with NEC2. Violating the
height above Mininec ground rule yields a source power of
396 watts and a load power of 340 watts (86% efficiency)
for a 1000 foot line, one foot above ground, on 20m. :-)
(While yielding a Beverage antenna gain of 13 dBi)

How would it work between two ships on a calm ocean?

Can the single-wire transmission line be modeled with EZNEC
if the height is greater than 0.2 wavelength?

Can it be modeled with NEC4? If so, could someone do it
and report the results?

If you want a really broad-banded Bazooka, use RG-174. :-)
Advantages: light weight for easy back-packing, no tuner
required, inexpensive coax, ... Hey, maybe I should keep
it secret until I market it for $100.

There was a outfit nr of years back even outdid the "Double Bazooka",
worked with ANY lengths of wire, garenteed less than 3:1 SWR.
Their secret was a 50 ohm, 100- watt non-inductive resistor in the
center plate. Got a GREAT SWR, but not terribly EFFECIENT!
They didn't last long after the ARRL/QST article described their
"MIRACLE" antenna ! As info, Jim NN7K

Model one with EZNEC to find out. At each end, put a few radial wires just above the ground to connect the source and terminating resistors to, and use High Accuracy ground. The Average Gain will tell you the total loss which includes resistor and ground loss. Click the Load Dat button to find the loss in the terminating resistor. From those you can get the amount of ground loss.

I don't think either program can model it. Single wire transmission line operation depends on an interaction among the field from the wire current, the insulation, and the air, that NEC-2 and -4 don't model. The wire insulation calculation provided by EZNEC and NEC-4 only calculates the effect of insulation on wire impedance, not on how the field launches from the wire. You might be able to do it with a 3D field solving program (which, last I heard, were in the $20k+ category).

RG-174 is great for some purposes.

Long, long ago I used it to feed an antenna (in the 5 MHz region) that had to be invisible. Its small size was a great aid to that task. A short piece of the stuff also makes an effective garrote because of the steel strands in the center conductor.

As everyone else has said (more than once), the "Bazooka" antenna is rarely worthwhile.

Egad, Cecil! It's evident I wasn't too bright years ago when I showed why the bazooka gets its meager increase in BW from resistive loss, not reactance cancellation. My scamming genes hadn't developed to the point where I even thought of marketing it instead of panning it. As you said, Cecil, with the higher loss available using RG-174 vs RG-17, think of how rich we could have become if we'd let the morons continue to believe what a great antenna it is, and sold em with 174.

Rather than holes in the bands, or loss of reflectivity of the ionosphere, I believe the high power SW BC stations in A-fricka have totally dehumidified the ground surrounding their antenna systems. The result is that the ground is sucking up all the energy rather than reflecting it. Therefore, instead of getting the inherent 6 dB gain from the ground reflection we're getting at least a 30 dB loss in signal strength from ground absorption. This condition is bound to continue until the heavy metal such as mercury suspended in the atmosphere rains down on the ground around the antenna systems to reinstate the ground conductivity to its natural state. Only then will the ground cease being absorptive and again become reflective. With the present state of the atmosphere it won't take very long for this to happen.

The only other reason for this phenomenon of lower signal levels is the increase in the inherent D-layer absorption due to the heavy concentration of heavy metal suspended in both the atmosphere and troposphere. If this trend isn't reversed soon the suspension will also gravitate to the ionosphere, in which case no sky wave signals will propagate and we'll be stuck with only ground-wave propagation. Now wouldn't that be a helova situation?

463. Re: Anodized Alumium for Antenna Elements

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-09 22:38:23 UTC
From: Jay in the Mojave <jay123a@qnet.com>
Message-ID: <115gmb22eo3rsb9@corp.supernews.com>
Source record: 79328
Cross-posted to: rec.radio.amateur.antenna,rec.crafts.metalworking

Hello Sir George and Howard:

Anodizing the aluminum is kind of over kill as I have measured new antennas and old antennas with 30 plus years of exposure to the elements. No difference measured.

What did throw me a curve was buying Anodized Surplus Aluminum Tubing in Burbank Ca, and making a vertical for the VHF Low Band. Ok no problem getting it together and should have tuned in a few minutes.

But no it was responding to a much higher frequency than the 31 Mc I wanted it to tune to. After checking and double checking everything and replacing the coax and antenna analyzer it still measured a way high frequency SWR null.

Now faced with the strong reality that this thing was gonna kick my a$$, after a hole day of going nutzoid. I got my old Simspon 260 VOM and measured continuity from all the elements. I found that one of the vertical elements had been anodized on the inside causing a no connection condition.

Cutting off a metal wire brush and putting the shank in Mr. 1/2 inch chuck, drill motor, and the 100 foot cord (I have given up on battery operated drill motors) the inside of the tubing was now nice and shinny bright aluminum.

The antenna tuned up as designed. So keep your eyes open when using anodized aluminum tubing. And I think this is why some antenna manufactures do not anodize their aluminum tubing. Plus the added manufacturing costs.

Jay in the Mojave

I would put them at the center
as I see buckling as the worst danger.
I have also done this with a 60 foot boom antenna
with no problem. I was forced into this position in the first
place because I have a fold over tower and eventualy stopped
using the top guy wires thru lazyness.

466. Characteristics of sloping G5RV?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-09 22:59:33 UTC
From: "Chuck W." <cwyatt@w3minds.com>
Message-ID: <1113087573.943082.178250@f14g2000cwb.googlegroups.com>

Typically I hear about mounting with the feedpoint high, and the ends low, but I managed to mount it with the feedpoint at about 35 feet, and one end at 60 feet, and the other end at around 35 feet, so I have kind of a sloping dipole.

Curious about what the characteristics of this antenna would be -- is it more of a cloud burner, or does the slope offer a lower angle of radiation?

Thanks for any thoughts!

-Chuck

If the tower is 4 feet across at the base, you may not have a problem,
otherwise - If you do that, be sure the tower is more than 60 feet from your
house - so it will miss the house when it falls.
Most of the water towers you see are a hundred feet or higher, but have no
guy wires, because the base is pretty wide.
guying at the top only may cause it to bow in the middle during a windstorm
to such a degree as to collapse.
I would guess the tower manufacturers would have wind and static loading
data available.
You have wind loading and the static loading due to gravity - which begs to
become dynamic.

try practicing with half-inch pvc water pipe - see where the guy wires do
the most good.

your idea of an impedence transformer at each end is interesting,
also, this website goes into some detail - and even goes as far as to
suggest using the earth as the single-conductor transmission line.

Hi Chuck, Depends on what bands you are using the G5RV. On 80 and 40M
you will have an omnidirectional cloud burner. On the higher bands you
will have some directional effects.
You could model this and see what effects the sloping has. Someone
will correct me, but I think a G5RV can be modeled as a 102' doublet.
Your average heigth is 48', so 40m may exhibit directivity.
You should have good results with a G5RV mounted this way at 60'
sloping to 35'. If that's what you can do, then go for it.

I particularly liked his "back-to-back limiters" which
allowed amplitude discrimination for AM signals. Didn't want
to hear that S9+30dB AM signal? Simply discriminate against
it and listen to all the others. I actually asked my Elmer
what a "back-to-back limiter" was. W5OLV just smiled. :-)

According to Rohn specs, a single set of guy wires limits
your tower to 40 feet maximum height - sorry about that.

This is really a complicated subject and off the cuff remarks and supposition are worthless.

The forces *can* be analyzed as uniformly distributed but usually, the wind pressure is stronger near the top, particularly if there is an antenna up there, which is the normal reason for a tower.

You might be inclined to say aha, then the top is the place for the guys. But, guys turn horizontal force into vertical force that tries to drive the tower into the ground. With the top and bottom restrained, then the middle might be inclinded to deflect horizontally under wind load. With it so moved, then the down force from the weight of the tower and the additional force from the guys can cause the tower to buckle.

Another concern is mechanical resonance. Top guying is going to make the top resemble a string on a musical instrument with the wind trying to pluck it. It has been my (sad) experience with a Cushcraft AV-80 tubular vertical that guying half way up, is equally bad. I had a resonance set up and the tubing bent to yield and broke in two right *under* the guys.

When I installed it I didn't have the data sheet but knew that it needed guys. So I guessed at 50% up. Since then I've acquired the data sheet and the recommendation is to guy about 2/3 up from the bottom.

The bottom line is to listen to the manufacturer.

There's a Double Bazooka currently on eBay for the "Buy it Now" price
of only $60.

Part of the sales pitch is:

"The Double Bazooka antenna was designed and developed by the M.I.T
staff in the 1940's as a radar recieving antenna. Its design was
modified for the hf amateur radio bands."

There's one born every minute...

Hi Bob
Actually that is historically correct about MIT and RADAR.
But the SWR reduction is where the reflected power is so low it doesn't matter.
And you pay dearly for it in signal strength.
As soon as you move far enough from resonance (dipole SWR >1.2:1 or so) such that the parallel-resonant network ("tank circuit") quits oscillating at the DRIVEN frequency, the whole thing falls apart.
And they're a pain-in-the-ass to built "just right", errors of <1/4 inch are bad news on 40 meters.
I know; Took seven tries to make two that resonated just right on 40.
On 160 the loss was such that I never got it to "ring".
I posted all the data here some time ago.
Walt once accused me of having "zeal" for taking data; I'm an experimental physicist.
http://www.hep.utexas.edu/mayamuon/
Like I said, build a good dipole carefully.
There is no free lunch.

I seem to remember from "structures" classes that the rule of thumb was
that if the solid diameter of a member was one tenth or more of the height
then the
member will break in normal compression mode. (Top loaded)
If the ratio of length to diameter was more then the member will buckle.
Seems like a good starting point to me. But then
that is the easy part since one would have to tension the guy wires to a
specific
force with multiple variables ! Note Tower manufacturers do not have to
introduce
safety factors in their calculations as would a crane or pulley manufacturer
where personel
are usualy in the area of use.Thus strength of material used must be on the
mark.
This is why I would guy at 30 feet and accept that movement at the top will

still happen
but with less moment of forces (wind loads) that would be around in the
event of no guys.

Did you ever take any ME courses Art?

Simplest back of the envelope approximation is 2/3 is best, ignoring
toewr resonance and lower wind as you get closer to ground level, so,
lower points would put more torque on the tower. With an antenna
mounted, it would move the optimal single guy point upward.

It's possible I may have this cimpletely wrong, if so, correct away folks.

Interesting, as I have measured antennas with only 2 years exposure that had .5 dB measured difference. A 432 MHz antenna scrubbed with a ScotchBrite showed a .6 dB gain increase.

So B as in B, S as in S, as we say here in Minnesota.

John Smith wrote:
"Do you happen to have a URL handy where I could view "Bulletin 74?"

I searched the web unsuccessfully, including some NIST sites which dictated schedules for clearing their files at certain file ages. But, I did find a reference to the famous bulletin in Keith Henney`s 1950 edition of "Radio Engineering Handbook". On page 132, Keith writes: "It is possible to calculate the true (l-f) inductance of some types of air-cored coils with a fair degree of accuracy. National Bureau of Standards Circular 74 has long been the most authorative source of such information. Some of the most useful contained therein are reproduced here."

Pages of information follow which include design charts which I can`t reproduce due to my limitations. Such information is not copyrighted as it is assumed the taxpayer has paid for collection of the information already, and should not have to pay for it a second time. That was pre Bush policy, of course.

You can probably borrow a copy of Keith Henney`s book in a library near you and delight ijn designing your own antenna coil. The publisher was McGraw-Hill.

Best regards, Richard Harrison, KB5WZI

Hi Richard,

Some background material:
"George Southworth was born in Little Cooley, Pennsylvania, in 1890 and became interested in radio while still in high school. He graduated with a degree in physics from Grove City College in 1914 and then studied for a year at Columbia University. In June 1917 he joined the Radio Section of the U.S. National Bureau of Standards and assisted in the preparation of the influential Bulletin 74 entitled Radio Instruments and Measurements, published in1918.
... [some time later]
"In 1931 he began a study of wave propagation in dielectric rods, although the project did not yet have official authorization. By early 1932, he observed wave propagation in a water-filled copper pipe. Theoretical analysis related to Southworth's experiments was carried out by John R. Carson, Sergei A. Schelkunoff, and Sallie P. Mead during 1932.
"Using high-frequency vacuum tubes imported from France, Southworth transmitted waves through air-filled copper pipes up to 20 feet long by May 1933. He later recalled that the first message sent through a waveguide was 'Send money.'"

==========

Roy, I've never head of a W8JK. You are confusing the issue.

The problem is concerned with a LONG balanced transmission line and its terminations which form part of the whole radiating system. And as we can agree it is incorrect to consider parts of the system in isolation.

To simplify the questions, wthout loss of rigor, it is best to consider the line itself as being lossless with matched terminations.

I have stated that power radiated from the system is independent of line length and nobody has disagreed. Indeed, a radiating power calculating formula from reputable authors (of which I was unaware) has confirmed this.

The power radiated from the system is identical to that radiated from a monopole or short dipole, of length equal to wire spacing, with a current equal to the current which flows in the terminations (ie., the load). The terminations actually exist.

Radiated power = Load current-squared times calculated radiation resistance.

That is obviously true down even to zero line length.

The implication is that radiation occurs only from the termination(s) and that no radiation occus from the line. But, I repeat, we must NOT consider the parts in isolation as do old wives.

You have stated that radiation from the line itself (in isolation) must exist in the plane of the wires because of the finite spacing between the line wires.

But we must consider only the far field. Not that in the immediate vicinity of the line and its termination.

I suspect that the radiation pattern of a LONG-line SYSTEM converges towards that from a monopole located in the position of the load.

Many of us are curious to acquire an idea of what the radiation pattern looks like.

You are familiar with programs which produce far-field radiation patterns. Do you know of a program which accurately produces the radiation pattern of a very long close-spaced, zero resistance, pair of wires terminated with a wire of length equal to wire spacing and including a load resistance equal to Zo.

Patterns, of course, will change with frequency. It will be necessary to statistically analyse results. Or just look at them from a common sense point of view.

From a practical engineering viewpoint it is quite sufficient to know what I innocently stated in the first place - the minute amount of power lost is the load's radiation resistance times load current squared and is independent of line length.

Employing the search term "Radio Instruments and Measurements" at:
http://www.kartoo.com/
you can make use of an unique, cluster based search engine that represents the next wave of sifting information on the Web.

You will find references to this tome (hardly a circular or bulletin) of more than 600 pages (you will also find book venders ready to sell this work for $20-$30). One NIST site contains a quote from Edison:
" . . . This is the greatest book on this subject that I have ever read, and I want to congratulate you and your Bureau on its production."

There are multiple authors. I cited one, George Clark Southworth, another was J. Howard Dellinger.

There are hard copies available through NIST's Historical Archives (try to get one though).

Well, you'd have to ask Mark Thorsen, WB0TEM, what equipment was used,
but the range is checked several times against the reference antenna
during each band we run, and is generally within .1 dB between checks.
Except that one day in KS. Boy was it hot.

I wouldn't bet absolute values are on the mark, but an antenna measured
against itself was reproducable. So I do believe the antenna improved
due to having the oxide scrubbed off.

Hmmmm. The top had does NOT seem to be such a good idea, at least not in
combination with the helical coil--with total element length as a helical
and evenly spread out.
If I just move a wrench in the yard around the antenna I get wide SWR
swings! (OK, maybe that is exaggerating a bit--but you get my meaning.)
The top hat seems to give the antenna an almost "magical ability" to couple
into any metal object of sufficient size, cars are noteworthy examples!!!

Hi Tom,

But the point of accuracy, even reproducible accuracy, requires a very absolute source to compare against. Sometimes that absolute is quite simple to achieve, but now you have upped the ante to 0.1dB. This implies a measurement accuracy of at least three times better; which, in turn, means you have access to a standard that can discern 0.8%.

To say you test the antenna "against itself" does not really say much when it comes to power and gain. That is no benchmark. The presumption here is that you have an external source of power that is constant. This then raises the same question. Over a span of time, what guarantees this degree of accuracy? By what method is it confirmed? That source's "absolute" power level needn't be an issue, but there is no way to escape casting that "absolute" requirement into another standard to confirm the fact of its stability.

Dear Butch - no call:
You will find any of the Tennadyne LPDAs to work as well as can be expected (for the number of elements used and boom length). The mechanical tolerances on their parts are so tight (desirable) that one needs quite a bit of hand-fitting. One should pay for the option that strengthens the boom where the largest element is placed. On the longer booms, one should use more of a truss than recommended.

One must use a balun right at the boom to mast transition in order to preserve a clean pattern. Most easy way to do so is to coil the coax connected to the front of the LPDA on a form that bridges the insulated coupling to the support mast.

Here on the back row, there's always been a hand raised in disagreement
on that point.

No argument that it's very, very small. But exactly zero - definitely
not.

>Indeed, a radiating power calculating formula from reputable authors
>(of which I was unaware) has confirmed this.
>
If you mean the Sterba reference, then please re-read it. All the endorsements of the formula that you quote are peppered with caveats such as "an approximation" and "providing that operations are confined to wavelengths other than those within the ultra-short-wave region."

This is for the very good reason that some small amount of transverse radiation does exist. Transverse radiation in the plane of the line is small because the vector components of radiation from the two parallel lines are equal in magnitude and almost exactly opposite in phase - but never exactly opposite.

I am probably the only person in this discussion who has actually USED parallel-wire lines "within the ultra-short-wave region". If you can maintain good balance, the losses due to transverse radiation are negligibly small for engineering purposes.

But to claim they are exactly zero is a physical absurdity... and I'll always disagree with those.

(Sorry, I'll have to be out of this discussion again for a while.)

To all:

It is my understanding that all gov't materials, since paid for by
taxpayers, are non-copyright.
Also, any material before 1923 would have expired copyrights and,
undoubtably, a significant amount of material will have been published
"public domain"; so, does anyone have a list of non-copyright materials
pertaining to antennas? Or, any ideas of how to obtain the information on
how to assemble one.
A website of non-copyright materials concerning antennas would be a great
asset to this community...

Regards,
John

Based on some of the other responses you received it may not be worth it but there is another type of coating for aluminum called alodyne which protects the same way as anodizing but is electrically conductive.

Alodine (R) coatings are not conductive. You can specify a "type 3"
coating that is thin enough that fasteners will usually punch through
the coating layer.

See MIL-C-5541 chromate conversion coatings.

I guess that you are concerned because there is only "one" trap pair
per element. I believe that in the Mosley antenna both the 10 and 15
traps are in the same housing. There is no requirement that there be
an external piece of tubing between the traps.

Tell me about it [g].

I was the engineer responsible for transferring the design of the then
new Phoenix Missile IMPATT diode transmitter from the development lab
to the production floor.

The transmitter had three stages: a single diode driven by a
phase-locked Gunn oscillator fed a three diode cavity that drove a 16
diode cavity.

The development hardware used aluminum cavities that were comprised of
two pieces, with third copper piece that mounted the sixteen diodes.
So there was one aluminum-to-aluminum and one aluminum-to-copper
interface in each sandwich. Since this was a product for the U.S.
military, "passivation" was required for all aluminum parts.

I won't go into the considerable amount of detective work that it took
to decide that despite being "conductive" Alodine and its ilk are not
suitable coatings for rf components.

Gold is your friend, if of course, it's thicker than a few skin
depths, which is another long story. [g]

Hi John, You write like you are in the 2nd grade. I am amazed that
you could pass the Amateur exams. The answer you gave to a technical
question was, read the TA-33 manual, and go back and study the License
Manual, both good advice. The way you wrote the advice makes one
wonder if you know what you are talking about.\

Ok. I'll give the details I remember, but be advised I didn't implement
Mark's system, I just assisted in using it.

The range has a source yagi for each band, that yagi has a low power AM
modulated signal on it (as I remeber, might be wrong on this). The
other end has a reference yagi off to the side from the test position.
A yagi with "known gain" is run against the reference yagi, and the
relative signal strength is measured. That gives us a known gain point
on the meter. A yagi is then placed in the test position and the
relative gain or loss is recorded. The "known gain" yagi can be put
back into the test position at intervals to check the calibration.
Obviously the absolute values may be suspect, but relative measurements
work well. The results also agree very well with YO predictions, with a
yagi in the 18.4 dBd predicted range being low by .3 as measured, which

is roughly what he expected to happen. Most more normal gain, 14 to 15 dBd for 432, were within .1 of predicted. Bands tested on this range were 144, 220, and 432.

Multiple prototype 2M and 70cm EME antennas that my partner and I built, stored safe from corrosion, tested the same +- .1dB with a several year gap between the tests.

What equipment he uses for the ratio measurement, and precisely how it is done, I don't know. I will attempt to contact him and find out if I can get this damn sinus infection under control in the next few days.

In the past I've used the Radio Shack wall stand-offs with a section
of galvanized 1.5" water pipe, and that worked fine to support an R-5
vertical, but the pipe is heavy and needs to be ground-supported, as
Tam inferred.

Thank you all for the information. I knew I could find good"stuff" out there.
The wind generator (not an antenna) I was planning has limited information available as to loads. ie. No Flat Plate or FPE numbers. The only statement is that the tower must take a 200 pound lateral thrust and not deflect more than six inches with winds of 200 mph. The Trylon T-200 tower specs. for my maximum wind speed area (from the chart at their web site),
shows that the T-200 will take a 42 pound lateral thrust at winds of 85 mph.
If 120 mph winds cause the wind generator to exert 200 pounds of lateral thrust, what speed of the wind will yield the 42 pound maximum lateral thrust that the tower will hold? Please show your work.

Experience is directly proportional to the amount of equipment ruined.

wrote:

Hi Tom,

The number of variables in the description of your (Mark's) method is
rather considerable, so I will remark by the parts you offer:

>The range has a source yagi for each band, that yagi has a low power AM
>modulated signal on it (as I remeber, might be wrong on this).

So far, fine.

>The other end has a reference yagi off to the side from the test position.

Commendable.

>A yagi with "known gain" is run against the reference yagi, and the
>relative signal strength is measured.

I might slyly point out how do you know the gain? It visits the age
old logical knot offered:
In a town of clean shaven men,
there is a barber who shaves everybody who does not shave himself;
who shaves the barber?

>That gives us a known gain point
>on the meter. A yagi is then placed in the test position and the
>relative gain or loss is recorded. The "known gain" yagi can be put
>back into the test position at intervals to check the calibration.

This method is called using a "transfer standard." As I offered, that
requires an absolute knowledge somewhere, and you have identified it
in this "known gain" yagi. However, the gain is actually immaterial
until you begin making claims of absolute gain. That is, most of this
correspondence is satisfied with relative gain comparisons as you
point out:

>Obviously the absolute values may be suspect, but relative measurements
>work well.

Quite true, however, you having once acknowledged suspicions you then
plunge back into the murky pool of absolutes:

>The results also agree very well with YO predictions, with a
>yagi in the 18.4 dBd predicted range being low by .3 as measured, which
>is roughly what he expected to happen. Most more normal gain, 14 to 15

>dBd for 432, were within .1 of predicted. Bands tested on this range
>were 144, 220, and 432.

Well, here we run counter to my experience with real life components. They varied by several times your 0.1dB, and this was often times for the same item tested repeatedly (I never measured any item less than five times and never five times repeatedly, in a row).

>Multiple prototype 2M and 70cm EME antennas that my partner and I built,
>stored safe from corrosion, tested the same +- .1dB with a several year
>gap between the tests.

OK, the method is good and robust, but your sudden departure from expected results are on the scale of 5 to 6 times the range of your typical error.

If this is to be attributed to oxidation on the elements, that still seems suspect. The oxidation is not lossy, and certainly is not sufficiently thick enough to shift the resonance. Oxidation is one of the charms of aluminum, it is self sealing.

I would offer that if the elements oxidized, so did the connectors (or connections). Simple, repeated connector matings (like swapping in and out for the range test) were sufficient to break bad contacts and make the difference which was attributed to scrubbing the elements. In the normal course of my calibration of various items with connectors, I always inspected and cleaned them first. N connectors have erosion problems that will give rise to variations outside of 0.1dB - comes from those threads. The "standard gain" antenna should be suffering from this erosion by now, but you don't report it.

This raises suspicions for me - you have too much fulfillment of expectations which is truly extraordinary. I have made thousands of calibrations of isolators, pads, couplers, meters and so on that have shown a gaussian distribution of results for premium equipment. Your range experience shows very little variation - much too little when we are talking about being within 0.1dB.

>What equipment he uses for the ratio measurement, and precisely how it
>is done, I don't know. I will attempt to contact him and find out if I
>can get this damn sinus infection under control in the next few days.

Well I hope you shake the infection off. Further details are unlikely to resolve this corrosion as it is too much a matter of "you had to have been there" kind of thing.

The reason some people don't know for sure
if they are going to Heaven when they die
is because they just don't know.

The good news is that you can know for
sure that you are going to Heaven which is
described in the Holy Bible as a beautiful
place with no death, sorrow, sickness or
pain.

God tells us in the Holy Bible how simple
it is to be saved so that we can live
forever with Him in Heaven.

"For if you confess with your mouth Jesus
is Lord and believe in your heart that God
raised Him from the dead, you
WILL BE SAVED." (Romans 10:9)

Over 2000 years ago God came from Heaven
to earth in the person of Jesus Christ to
shed His blood and die on a cross to pay
our sin debt in full.

Jesus Christ was born in Israel
supernaturally to a virgin Jewish woman
named Mary and lived a sinless life for
thirty-three years.

At the age of thirty-three Jesus was scourged and had a crown of thorns pressed onto His head then Jesus was crucified.

Three days after Jesus died on a cross and was placed in a grave Jesus rose from the dead as Jesus said would happen before Jesus died.

If someone tells you that they are going to die and in three days come back to life again and it happens then this person must be the real deal.

Jesus Christ is the only person that ever lived a perfect sinless life.

This is why Jesus is able to cover our sins(misdeeds) with His own blood because Jesus is sinless.

The Holy Bible says, "In Him(Jesus) we have redemption through His blood, the forgiveness of sins..." (Ephesians 1:7)

If you would like God to forgive you of your past, present and future sins just ask Jesus Christ to be your Lord and Saviour.

It doesn't matter how old you are or how many bad things that you have done in your life including lying and stealing all the way up to murder.

Just pray the prayer below with your mouth and mean it from your heart and God will hear you and save you.

Dear Jesus Christ, I want to be saved so that I can have a home in Heaven with You when I die. I agree with You that I am a sinner. I believe that You love me and want to save me. I believe that You bled and died on the cross to pay the penalty for my sins and that You rose from the dead. Please forgive my sins and come into my heart and be my Lord and Saviour. Thanks Lord Jesus Christ for forgiving me and saving me through Your merciful grace. Amen.

Welcome to the family of God if you just allowed God to save you. Now you are a real

Christian and you can know for sure that
you will live in Heaven forever when this
life comes to an end.

As a child of God we are to avoid
sin(wrong doing), but if you do sin the
Holy Bible says, "My dear children, I
write this to you so that you will not sin.
But if anybody does sin, we have one who
speaks to the Father in our defense Jesus
Christ, the Righteous One."

Those of you that have not yet decided to
place your trust in the Lord Jesus Christ
may never get another chance to do so
because you do not know when you will die.

This means that if you die without
trusting in Jesus Christ as your Lord and
Saviour you will be forever separated from
the love of God in a place called Hell.

The Holy Bible descibes Hell as a place of
eternal torment, suffering, pain and agony
for all those who have rejected Jesus Christ.

The good news is that you can avoid Hell by
allowing Jesus Christ to save you today.
Only then will you have true peace in your
life knowing that no matter what happens you
are on your way to Heaven.

Servant of the Lord Jesus Christ,
Internet Evangelist
Ronald L. Grossi

As I state later, the absolute gain number is suspect. And I quoted
"known gain". That's a clue to it really being a variable to a certain
extent.

And, as you well know, having been in the business since day minus one,
it is possible to build standard gain antennas for UHF and microwave
that will pretty much dead on every time. They are available in many
texts you already probably own.

The corrosion was on an antenna that had not been in the barn, it had been used for 4 years in an EME array, and was fairly well corroded. We tested it to see how it would compare to the protected identical prototypes, and then we cleaned it for a second test run. And the connectors are always N connectors. 'nuff said.

The standard gain antennas are also not left out in the rain, and do not live in a city.

Thanks for getting me to call him and review how it was done. I spent an hour and 3 quarters getting up to date. And he is about to get 500 watts at the feed point on 2304 going. That is a fairly impressive amount of juice homebrewed on that band. Only 4 transsitors to do it. Ain't technology wonderful? And he has a 32 foot homebrew dish.

Hi Tom,

Not one of their numbers against the characteristics. However, I am
familiar with what you describe as the characteristics.

It is a tuned AC voltmeter, commonly used for SWR measurement in
slotted lines connected to a the detector where the source is
modulated at 1KHz. The meter is tuned to 1KHz and has a very high
gain and selectivity. This allows it to employ a variable gain, by
10dB switch steps (and a variable knob to set zero, or the reference).
The scale is read in combination with the attenuator (gain) switch and
thus the scale offers considerable resolution, easily 0.1dB and
better. It is probably an HP-415.

I've calibrated these too (Boonton, I think, also built them, but as
Boonton was acquired by HP, it isn't a remarkable difference).

So for relative gain it's possible, in your opinion, to measure +- .1dB
with this, if properly used?

Dear "fcrumpler" no call, no location:

Theoretically, the force produced by moving air impacting on a flat plate is proportionally to the square of the air's velocity. However, in the real world where one should appropriately deal with wind gusts and variability of materials, things are not so simple. Safety factors should be used. Accommodation for the significant vibration to be caused by your proposed "wind generator" must be made.

Numbers supplied by some vendors involve no safety factors.

You need to retain a Professional Engineer licensed in your state or province who is experienced with vertical wind structures. This is certainly the case if the proposed structure is able to damage other property or endanger living things.

It is not safe for you to scale the numbers that you have. Too little information. Too much risk.

So he's using decent equipment. Whether it's used correctly is another matter. I'm betting he did a good job, given the results I've seen, and what I know of him.

But you are correct to be be skeptical on the results.

So, you're saying that anyone could republish a book like "Moby Dick"
and sell it as their own since it was published before 1923 ?
I'm no lawyer, but I believe copyright live on. Patents expire.
If you're just wanting to build an antenna that someone else thought of
first
then you just 'do it' - just be careful about patent infringements if you
try to sell those antennas.

The reason some people don't know for sure
if they are going to Heaven when they die
is because they just don't know.

The good news is that you can know for
sure that you are going to Heaven which is
described in the Holy Bible as a beautiful
place with no death, sorrow, sickness or
pain.

God tells us in the Holy Bible how simple
it is to be saved so that we can live
forever with Him in Heaven.

"For if you confess with your mouth Jesus
is Lord and believe in your heart that God
raised Him from the dead, you
WILL BE SAVED." (Romans 10:9)

Over 2000 years ago God came from Heaven
to earth in the person of Jesus Christ to

shed His blood and die on a cross to pay our sin debt in full.

Jesus Christ was born in Israel supernaturally to a virgin Jewish woman named Mary and lived a sinless life for thirty-three years.

At the age of thirty-three Jesus was scourged and had a crown of thorns pressed onto His head then Jesus was crucified.

Three days after Jesus died on a cross and was placed in a grave Jesus rose from the dead as Jesus said would happen before Jesus died.

If someone tells you that they are going to die and in three days come back to life again and it happens then this person must be the real deal.

Jesus Christ is the only person that ever lived a perfect sinless life.

This is why Jesus is able to cover our sins(misdeeds) with His own blood because Jesus is sinless.

The Holy Bible says, "In Him(Jesus) we have redemption through His blood, the forgiveness of sins..." (Ephesians 1:7)

If you would like God to forgive you of your past, present and future sins just ask Jesus Christ to be your Lord and Saviour.

It doesn't matter how old you are or how many bad things that you have done in your life including lying and stealing all the way up to murder.

Just pray the prayer below with your mouth and mean it from your heart and God will hear you and save you.

Dear Jesus Christ, I want to be saved so that I can have a home in Heaven with You when I die. I agree with You that I am a sinner. I believe that You love me and want to save me. I believe that You bled and died on the cross to pay the penalty for my sins and that You rose from the dead.

Please forgive my sins and come into my
heart and be my Lord and Saviour. Thanks
Lord Jesus Christ for forgiving me and
saving me through Your merciful grace.
Amen.

Welcome to the family of God if you just
allowed God to save you. Now you are a real
Christian and you can know for sure that
you will live in Heaven forever when this
life comes to an end.

As a child of God we are to avoid
sin(wrong doing), but if you do sin the
Holy Bible says, "My dear children, I
write this to you so that you will not sin.
But if anybody does sin, we have one who
speaks to the Father in our defense Jesus
Christ, the Righteous One."

Those of you that have not yet decided to
place your trust in the Lord Jesus Christ
may never get another chance to do so
because you do not know when you will die.

This means that if you die without
trusting in Jesus Christ as your Lord and
Saviour you will be forever separated from
the love of God in a place called Hell.

The Holy Bible descibes Hell as a place of
eternal torment, suffering, pain and agony
for all those who have rejected Jesus Christ.

The good news is that you can avoid Hell by
allowing Jesus Christ to save you today.
Only then will you have true peace in your
life knowing that no matter what happens you
are on your way to Heaven.

Servant of the Lord Jesus Christ,
Internet Evangelist
Ronald L. Grossi

Here is one page on the net, from a university, if you research it, you will find this page seems accurate. The library of congress page contains info to this also...
http://www.unc.edu/~unclng/public-d.htm
Indeed, the examples of non-copyrighted works is not complete, there are other ways a book is/remains un-copyright-ed.
I think I did see Moby Dick as one ebook freely available on the net, and yes, I believe the copyright has expired on that book...

Since you mentioned Moby Dick, I went ahead and searched the University of
Virginias' ebook library, it is there. I think you will probably need the
"Microsoft Reader", it is available from the microsoft site... if you need a
URL just ask...
Here is the URL to Moby Dick if you wish to download it:
http://etext.lib.virginia.edu/etcbin/ot2www-ebooks?specfile=%2Ftexts%2Fenglish%2Febooks%2F
ebooks.o2w&query=Moby+Dick&docs=TEI2&sample=1-100&grouping=work

You can search their library of 1800+ ebooks with expired copyrights at:
http://etext.lib.virginia.edu/ebooks/

There is nothing inaccurate in that description as far as I know.

Let's be fair about the Double Bazooka: It does exhibit a broader SWR
bandwidth than a dipole antenna.

I've now used the 160m coaxial inverted "L" described by Ted Cohen N4XX
in the January, 2000 issue of CQ Magazine. It has been up for about
four years, during which time I've worked just about any exotic DX which
has appeared on the bands--even FT5XO.

The antenna is simply half a double bazooka and it runs vertically 65 feet and horizontally a little over 62'. The entire 200 KHz of the 160m band is covered with SWR under 2:1. Of course the fact that I have about 6,000 of radials under the thing may help more than a bit. Can I assume that since the antenna is only half a double bazooka that the loss of power in using it would be roughly half of that using a double bazooka dipole?

I can often work EU stations with just 100w. I could seldom do that from my Cincinnati QTH in the late seventies and early eighties using a 60' omega matched aluminum tower with TH6DXX as top loading.

Cecil, !5DXP wrote:
"According to Rohn, a single set of guy wires limits the tower to 40 -
feet maximum height - sorry about that."

Well, it depends on the Model No. and how you will load the tower. It is best to follow thw manufacturer`s recommendations to the letter.

There is a length that you can stack which will endure without guys in most cases. Towers usually come in 20-ft. sections. Often one or two sections is all it is safe to use without guys. Windloading the tower is expected to withstand, often determines space between guy points.

Wind exerts force on the tower and its appurtences, often expressed in a sum of pounds per square foot on the area facing the wind.. Resistance (drag) produces a differential pressure on items in the wind. Force is proportional to the projected area in the wind, and varies with the shape and roughness of the item in the wind. Windload on a tower is not uniform. The wind usually blows harder at higher altitudes. Wind tries to turn the tower over but until something yields, it is in equilibrium and the summation of of forces about the base of the tower is zero. The summation of torques is zero.

Guywires exert force in yje only way they can. They have tension in the direction of the wire. This may be resolved into vertical and horizontal components. This prevents movement and increases base loading when the wind blows.

Pressure on items in the wind (pounds per square feet) is a function of the square of the wind velocity (miles per jour).

One formula considered useful is named "Ensewiler" which is said to give:
22.5 psf = 85 MPH
45 psf = 134MPH
60 psf = 155MPH
75 psf = 173MPH

Best regards, Richard Harrison, KB5WZI

Sorry to keep repling to my own posts, but like to give as complete info as
I can, I should have mentioned this above, it is a repository of over 15,000
ebooks, mainly in plain text format, and many classics with expired
copyrights, and done mostly by volunteers...
http://www.gutenberg.org/

With a scanner and "Fine Reader" software, copying any book to ebook format
(.pdf, .lit, .txt, etc.) is a snap! I wonder how many hams are out there
with relevant-expired copyright material right now?

Your belief is mistaken. Copyrights expire. They always have (under
U.S. law). The duration of copyright varies, reflecting changes in
the law.

Get the details (at least as far as U.S. law is concerned) at the
Federal Government's copyright-office web site:

http://www.copyright.gov/

If a work was originally created after 1/1/1978, its copyright applies
for the life of the author plus an additional 70 years.

Works created prior to 1/1/78 were originally granted a copyright of
28 years, which could be renewed for an additional 28 years. The 1976
Copyright Act extended the duration of the renewal period to 47 years.
There are further complexities (many of them) as Congress has seen fit
to (some would say "has been bribed with large campaign contributions
to") further extent and expand copyright protection over the past few
years.

Works which were originally created prior to 1922 - i.e. more than 56
years prior to 1/1/78 - have falled into the public domain, as both
their original 28-year copyright, and a subsequent 28-year renewal
would have run out prior to the date on which the laws changed.

Many works created in the 1940s and 1950s have also fallen out of
copyright protection, as their original 28-year copyright terms were
not renewed. Automatic renewal of copyright didn't kick in until the
1990s.

[Disclaimer: I Am Not A Lawyer.]

Dave:
Yes, I agree, your information seems very linear to my own understanding.
And, yes, I too am cynical of congress and its' motives here. I certainly
support an authors' sole ownership of his intellectual material, and I am
willing to acknowledge a right to his immediate/living family. When it gets
out to his grandkids, I believe there is a greater argument; that is the
publics right to amass knowledge is of a greater importance than giving the
grandkids a free ride and free money, not to mention the media organizations
who exploit these laws to the detriment of societies goals and needs...
A free ride by the grandkids is probably not to their benefit anyway--one
can only truly appreciate that which he/she has himself/herself earned....
But hey, that is only my personal opinion...

Regards,
John

Hi Tom,

As I've offered, the test protocol is very precise, and the
instrumentation (as far as has been discussed or inferred) is up to
the resolution. However, many mistake what accuracy, precision, and
resolution mean.

Resolution is the number of digits in your reading. It usually
implies that you can read more digits than you report. So, to say you
have measured a voltage to be 1.5V means that you have an instrument
that can read in hundredths of volts.

Precision is the repetition of readings. High precision means your
measurements all can be reported as 1.5V because they vary no more
than 4 hundredths of a volt in readings around the reported value (or
by more fancy regression techniques).

Accuracy is how far from actual your report is. It is enough to say
that resolution and precision are not accuracy, but that they are
necessary components of accuracy.

Insofar as the range goes, it remains to be seen if it has been
calibrated in its own right. The test is not necessarily found in
absolutes, but rather in its response to perturbations. In other
words, inject a known variable and measure its ability to support a
report that faithfully records the value of that variable as evidence
of its robustness. You have to perturb the system with small changes
as well as large changes to see if it is linear in its response. This
is not easy and makes great demands upon not only the instrumentation,
but the ingenuity of the tester. Then you repeat the tests from a
different angle to see if it is symmetric. Then you test for
background contributions - noise (actually this is probably best done
first as it sets the boundaries of your low end and defines part of
the dynamic range).

You do all the above, and then some, pool the results and describe
your limits of error. Test results that are reported without knowing
the limits of error are not very informative. Hence, when I hear that
readings are repeatable to 0.1dB for UHF and I hear nothing of the

range of error (I must presume that it is no greater than 0.033dB); then I am more than skeptical because 1% accuracy in power determination is the extreme of very tightly controlled laboratory conditions.

That there are repeated measurements in the field to this level of precision is suspect because there is very little instrumentation AND combinations of many pieces of gear that come close. It takes only two pieces of 1% gear to create a situation that is at best 1.4% accurate and you are already crossing the 0.1dB threshold. For those trying to balance the ledger, a 1% accurate determination requires a method that is at least 3 times more accurate. The usual aggregation of error arrives through RSS (root sum square); some may like to gild their prospects and compute RMS (root mean square) and if they are lucky, this is not far off. Given enough results, luck washes out to sea and RSS dominates. Given enough results that conform to RMS, then you find you have qualified your methods and instrumentation to superlative standards.

OK, I am going to stick my neck out here. Basically you have three possible arguments here:
1) God created all which is possible to see, most likely from the fabric of space itself (but why hasn't he made himself known to all, in a physical sense?)
2) You can take a handfull of glass, plastic, metal and rare earth elements, toss 'em into a mud puddle, come back a few million (billion?) years later and start pulling out microwaves, TVs, cellphones, etc. (since these items are much more simple than a living lifeform we certainly should have dug some up by now!)
3) We are an experiment by some alien race(s) and somehow lost all memory of the event (but then, who made the aliens?.)

Personally, I find no. 1 & no. 3, of the above, the easiest to believe.

Regards,
John

Just about all you need to know is when Mickey Mouse was copyrighted. When it was about to expire, the folks at Disney, with the help of generous campaign donations (known elsewhere as baksheesh) of > $6 million, got a nice bill through Congress (the Sonny Bono Copyright Term Extension Act) to extend the term of protection by 20 years for works copyrighted after (hee, hee) January 1, 1923. Mickey's copyright of course began after this date.

Copyright holders who own fewer Congressmen or are unfortunate enough to have copyrights that predate Mickey will just have to live with shorter terms. Hey, it's the best government money can buy.

The G2FHF Skyranger Pro is now in production and available for purchase. It is a multi-band groundplane antenna and is very efficient. It has been undergoing testing for several months in a very windy location and has stood up to everything that mother nature can throw at it.

The Skyranger Pro comes with a two year wind damage warranty and after sales support that is second to none.

Take a look at the Skyranger Pro at: www.g2fhf.com

Thanks

Jon Illsley G2FHF

In a similar light, and remembering that all politics are local, I
never cease to be amazed at how inexpensively one can buy a local
county board of supervisors member. We really do have democracy;
almost anyone can afford one.

We hams worry about getting signals through a few meters
of transmisssion line.
How about doing it through a few thousand kilometers,
under an ocean,
without a computer model,
and finally getting it to work?

The USA PBS TV network is showing a new program,

"American Experience: The Great Transatlantic Cable"

tonight (April 11, 2005) at 9pm EDT.

If you can't get PBS, a google search for
"Transatlantic Cable" "Cyrus Field"
brings up several links that look promising.

Cheers, 73,

Ron McC.

I'm not sure I understand your point about copyrights.

Even if a copyright has expired or never existed in the first place,
anyone who gives you a printed piece is going to charge for paper and
ink -- all the manufacturing costs involved in a printed piece.

Or, if you're just looking for web materials, it costs money to put up
a web site. You'll be charged to help defray those costs.

What are you expecting?

I am building my first antenna for the purpose of receiving WWVB (60 khz). The antenna is 1 meter square wound with 6 turns of RG6. I'm going to be using a FET for the preamp (very high impedance).

Can someone explain to me the concept of a coupling loop. I see references to it all the time, but no ones explains WHY we should use one. Why not connect the receiver to the mail loop? What is the physics behind the coupling loop?

I know this is a very basic question. Thanks to anyone who will take the time to explain or point me to a good article.

Stephen

Expect the PBS presentation to be excellent, as usual.

For great information in clear, concise form, the "Lenkurt Demodulator" was almost unbeatable. The topic of its January 1968 edition was "Undersea Cable". This edition was also included in Lenkurt`s 2nd book of reprints.

History and technical aspects are covered. First transatlantic cable between Britain and America was placed in 1858, lasted 20 days, carried 732 telegraph messages, and saved the British government 50,000 pounds it is said.

It took sixteen and a half hours to pass a 99-word message from Queen Victoria to President Buchanan. The next cable was laid in 1866 and lasted.

Best regards, Richard Harrison, KB5WZI

You ought to see what old physics texts, like Feynman and Hibbs or Morse and
Feshback sell for.
Oh well. Goes to show ya, the classics keep their value!

<headscratch> But Nature already has their equivalents.

TV as an entertainment has its counterpart in the chaos patterns of Nature;
rain, wind and flowing water.

Cellphones as a means of communication have their equivalent in the
long-distance communications of wolves and howler monkeys. (Closer to
walkie-talkies, actually... five-mile range, easy.)

And as for a microwave... <points straight up> The sun puts out microwaves
every day.

Bob:
You are living in the past my friend!
1) It costs nothing to make works available to the gutenberg project.
2) There are other endeavors, such as gutenberg (some colleges request help in obtaining materials, Virginia is only one)...
3) There are excellent peer-to-peer filesharing networks (Take a look at Winmx--it guarantees no spyware or malware in the app)
4) IRC allows direct DCC SENDS of data from one chatter to another. (this begs for someone to set up an amateur chat room anyway--MIRC is an excellent IRC chat client.)
5) There are free Web Hosting ISP's on which you can host data, files, etc.--all you need to know is HTML markup language and an FTP client (ask your kids/grandkids--they can set it up for you--if not, I will give some assistance.)
6) Ebooks can be emailed and shared.
7) etc., etc., etc.
The only excuse of why not to is ignorance and lazyness...

Regards,
John

Actually, books published from approx. 1938 back will have expired copyrights (before 1923 is just an absolute!)--there are ways to research any certain-given work (a search of the internet will provide these, and the library of congress provides some help itself with answers to email questions)--and I would most certainly suggest doing this before releasing any document as public domain...

This idea takes some getting used to--we all learn old wives tales which, if we are not careful, replace fact with fiction in our combined knowledge...

However, there is another reason why many are not knowledgeable of the fact knowledge itself was/is intentionally meant to, eventually, be placed within the publics domain. This reason I tend to refer to as, "The Control Freak Factor." A group of people who for one reason or another tend to attempt to halt, make impossible, obfuscate, and hinder the attempts of others to disperse knowledge and learning. Why they do this and what their motivation is, is beyond my comprehension.

Perhaps the reason is as simple as--given they feel such little control over their own lives they seek to control others...

Think about it, I believe you will realize you have seen this behavior before--both here and elsewhere...

Regards,

John

The best rearrangement by far, for a G5RV, is to use a 600-ohm open-wire line all the way from the dipole to the shack. With a few feet extra just as a precaution.

You could also beneficially increase the length of the dipole if you have enough room in your back yard. Another 10 or 20 feet would do no harm.

I'm sure all of the above exists, but it sounds like you are basically
for people working for free and not being compensated for their labor.
I'm about as damned-liberal as anybody on this group, but I believe
people who create intellectual property should be paid for it, and if
they want their kids and grandkids to benefit, so be it, and any
deadbeats outside the family who want to glom on to it for free, to
heck with 'em.

There are way too many folks who want free music, free film, free
books, free everything -- but if we stop compensating people who
create intellectual property, it will simply stop being created.

The (inappropriately named) Pacific coast where Danny lives has fair-sized waves almost constantly, particularly in the winter. When they break along the shore, a very fine mist of salt water droplets is created, and those drift for a long distance. In the winter, the prevailing wind direction is from the west, so the salt water mist is blown farther yet. The result is that the air itself contains a suspension of salt water. Aluminum corrodes fairly quickly, and good sized bare copper wire turns into a blue powder in a year or less. Where I live, in the Willamette valley of Oregon which is about 70 miles inland, it rains pretty constantly from about October through June -- not an extraordinary amount, but everything outside stays wet for the whole winter because of the lack of direct sunshine and the frequent rain. But aluminum lasts forever and so does copper, which only gets a thin, dark oxide coating. It's the salt water suspension that's the killer on the coast.

>But hey, that is only my personal opinion...

Well, that was pretty much the opinion of the Founders who set up the
legal structure for patent, copyright, and trade-secret protection.

The original motivation and justification for these sorts of law -
which have the effect of placing Government law-enforcement power in
the service of private individuals - was *not* to ensure the
enrichment of the inventors and authors. The original goal was to
increase the public good.

The reasoning is that by providing inventors and authors with a
limited protection of their creative works (i.e. exclusive rights,
for some period of time), it would motivate inventors to invent and
also to reveal their inventions to others in detail (the latter being
required for a patent) rather than keep their inventions secret.
Similarly, it would motivate people to write, create paintings, etc.

The legal protection was made limited in time... and I believe that
this was done specifically so that the inventions and creations
would continue to enter the public domain so that other people could
build upon them in the future, further enriching our cultural and
technical heritage.

A tradeoff was offered for those who wished to keep their inventions
secret, and maintain an indefinite "lock" on the exclusivity. The
alternate to a patent (which requires disclosure) is a trade secret.
The way that the law was originally structured, was that a trade
secret had to be kept *secret* in order to be protected... i.e. via
physical protection, legal nondisclosure agreements with the parties
to whom it was revealed, etc. A trade secret did not carry with it
any protection against independent re-invention or reverse

engineering. If you invent a better widget, keep its details secret, make it for several years, and then somebody independently re-invents the same device or process, you didn't have the legal right to prosecute them or shut them down.

Unfortunately (in my opinion), both copyright and trade-secret protection have been excessively widened over the past few decades. Copyright has been repeatedly extended to the point that it's now nearly unlimited in duration... literary inventions which have been part of American culture for many decades are still "locked up" as the commercial properties of the licensees of their authors. Similarly, "trade secret" protection seems to have been widened, to the point where companies feel free to ask the courts to shut down discussion and distribution of information involving the independent re-invention or reverse engineering of technologies that those companies feel is proprietary, even if none of the people involved in the discussion or reverse engineering are under any sort of trade-secret agreement.

Seems to me that the pendulum has swung too far in the direction of "protect the revenue of the inventors and authors" and too far away from "promote the greater public good."

wrote:

>but if we stop compensating people who
>create intellectual property, it will simply stop being created.

Hi Bob,

This assertion is untested by simple virtue of the extension of
copyright, and the continued abuse of patents. Being untested does
not mean that it defaults to being true.

Insofar as left/right/liberal/conservative politics go, Ben Franklin
was very much against patenting. In his era, plagiarism was rife, but
its penalty was weighed against purpose and claims and punished in the
form of opprobrium. You were far more likely to be sued for slander
than stealing ideas. Back then, if you couldn't pay the fine, they
threw you in the slammer.

But back to the assertion, there is every proof that this is simply
not the case. One of the chief contentions that America is shipping
its software jobs east (the far east, not Jersey) is that Asians will
soon crowd the field with better programmers (or simply more, cheaper
programmers) who will flood the capitalist market with their product.

Creativity being what it is, and what intellectuals do, such product
that is free and unencumbered has already washed the Asians out like a
tidal wave. I can point at one example of creativity that confounds
the monetary need for patent or copyright:
http://sourceforge.net/
where you and others may observe more than 98,000 software packages
are being offered for free (this is NOT crippleware) that are being
built by more than 1 Million designers (creative individuals). They
do ask for pledges, but this is not a condition of use.

The Chinese don't need more programmers to burn illegal copies of M$
Office, but neither do I need to fly to Shanghai to buy them. Instead
I can download Open Office for free (and certainly at less hazard to
asian infections). Do I breathlessly wait for the next iteration now
called Longhorn? That horse is so lame, M$ hasn't realized that the
field has left it behind. If a million Indian Engineers could put it
on wheels with a hemi under the hood, it still wouldn't pay their
wages in rice when it hits the market. M$ daily pays the cost for
exclusivity that eclipes copyright or patent. As far as creativity
go, copyright and patent offer abysmal return unless you are a one
note symphony composer.

The ONLY software I have ever purchased in the last 10 years was for Agent (the newsreader I am now using to post to this forum) and Outpost Firewall. Both items were to protect me from the third piece of software I bought, M$ Win2K Pro which could now be easily replaced with Linux (which I now build custom business systems on). Absolutely every application that is mainstream can be replaced and upgraded to for FREE.

In the spirit of compensation, not to the individual(s) who designed Open Office, but to the community at large, I have contributed my own Web Search Engines for FREE. My effort to produce them expended as much time, but far less cash in my pursuit of 5 patents (ego certificates).

If any want to argue that this is far different from Mickey Mouse protection, I would offer that even if his copyright expired, there would still be protection through Trade Mark, and Licensing agreements. Really, the laws are manifestly and explicitly for intimidation alone.

You can be sued for distributing the image of Moe Howard, but sky through with Abraham Lincoln's mug on a T-shirt. This is not about creativity, merit, or intellectual worth. It is simply about government sanctioned monopoly (and again, manifestly and explicitly so). As TR observed 100 years ago, expanded monopolies are bad for America.

Hi all, and thanks for the info.
Yes, the mast will go from the ground up! I thought about some sort of a hinge at the base, but sounds too complicated, so will just pull it up from an upper story window.
Of course, and advice is greatly appreciated.

GAD!

I had forgotten that white elephant. Thanx Wes.

Tom,

It is pretty much in the same class of expanded range, 1KHz tuned AC
Voltmeters. As long as you reference and return to a Cardinal point
on the scale, accuracy you describe can be supported.

In fact, this class of instrumentation is probably the best leverage
to building a very good RF lab. You can spend more, you could even
find equipment that does most of the grunt work for you, but it is
still a long shot that you will obtain more accuracy.

Accuracy is steadfastly bound to method and this style of
instrumentation reveals an example of method thought out and polished
with the best of engineering thought.

Since you're wanting to make it black to match other accouterments on your vehicle, consider that most, if not all, black-dyed anodization will fade in the sunlight, and it doesn't take all that long. In addition, depending on the aluminum alloy, the "black" may not be all that black to begin with. Why not instead give the antenna a coat of automotive enamel or lacquer? You can either mask off areas that need to have electrical contact, or scrape them after painting. Perhaps you can paint after the antenna is assembled. That way, you can get a color that really matches other items.

Cheers,
Tom

Personally I find that #1 is the easiest to believe.

I have a hard time accepting the we are an experiment of an alien race
considering the vastness of space. #2 is nearly impossible. While we
have made great strides in understanding what the make up of the DNA
strand, we still cannot create one or determine how the amino acids
form the DNA chain. The basic steps of evolution from the primoidial
ooze to first single cell organism. I mean if we can't go from ooze to
a single sell then how can we derive from single cells?

Pressing my neck to the chopping block a bit further...

Jesus was a truly amazing fellow...
He was a fellow I would most certainly would have liked to make the
aquaintaince of, a person I would have been proud to have called a friend, a
person I would have trusted with my life--indeed, my only fear is that he
would have rightly found fault with me.
Personally, I find the Dead Sea Scrolls almost positive evidence that he did
exist (OK, I have a hard time with "Son of God", but hey, he is at least as
great as any other "Enlightened Man." And, I can make this by "Leap of
Faith.") His only real enemies seemed to have been self-serving, envious,
greedy, evil B*st*rds, and a Gov't.
In this life, I have met some nice people, and uncounted individuals who
have led me to seek a higher road, but none as great as the image of
Jesus--he leads me to better efforts on a continuing basis, a never ending
quest... on the outside chance that he is only a "myth", hey, "Whatever
works!"

Regards,
John

Once long ago I was driving down highway 101 in my VW squareback, operating mobile CW late at night on 40 meters. Rig was homebrew, about 8-9 watts output (10 watts input). Antenna was a CB mobile whip on a bumper mount, base loaded with a coil wound on a powdered iron toroid core, Q about 200 - 250. Worked JA, solid copy. Yea, that salt water does wonders for a vertical.

James:
The only examples of "things" comming to existance WITHOUT a thinking mind
constructing the design, are the universe and life on Earth.
Since I am simply without sufficient examples to draw a logical conclusion
from, or proof of the underling "law" and methods which are at work, my best
guess is all I have... I concede it to be, at best, a poor one...
But, I have NEVER seen proof that matter and life come into existance all on
their own--by purely random chance. I expect the answers all lie in the
termination of my Earthly presence... if there are any to be had at all...
Or, perhaps, by those who will come after me...

Regards,
John

Whether by creation or by evolution at this time to believe in both
requires faith that either event actually happened. When in the
absence of factual data to support one's belief, faith that an answer
will be found is all there is.

In religion the faith in that one day, usually after our physical
death, the answers will be su pplied. In science there is the faith
that proper diligence and carefu studying of the data and evidence
will lead to the conclusion and answers to theories and postulates.

In all both science and religion have faith. Each to their own ends.

For most people these questions will be answered in an after life of
their chosing. Others the only answers are now and in their lifetime.
They do not believe in an afterlife.

Hi All,

In today's news, from the Seattle Times:
"'My belief is that open-source software is going to help drive
the acquisition cost of software down toward zero,' he said, a
shift that will require software companies to move 'over to a
maintenance and support model.'"
and this is a quote from Martin Taylor, Ballmer's chief of staff at
M$.

Now, taking that cue about future trends in protecting the rights of
those who create intellectual property, you may notice that patents
and copyright have ceased to have market leverage in an industry that
is content dominated. On the other hand, maintenance and support are
strictly labor centric. How long do you think 1million Chinese will
take to hone their mid-west accent? How long do you think it would
take you to brush up your Mandarin or Cantonese?

The economy of off-shoring is not found in how many calls the Chinese
Help Desk can answer, but in how many answers the Chinese Help Desk
can make understandable.

Nope it just does means we do not have all the answers and evolution
is still a theory in m any parts of it whole. There is insufficient
evidence to make a case for or against all or parts of evolution.

The acceptance of the whole of evolution is based on parts that have
been proven by observation and study. Beacuse parts of the theory are
true does not mean the sum of its parts are true.

Again to accept the whole of the theory of evolution with its missing
pieces is a leap of faith. Faith that at some time the evidence will
be there to prove the theory. Is that faith any different than that of
one who believes in a creator? How a creator did what he did is still
unprovable and may never be proven.

In time Evolution may be proven is some form or manner. We may
discover how life became on this planet. How it progressed and ho wit
changed. Maybe some resons as to why change and diversity. I doubt
science will ever discover why it all started in the first place! That
part of why is beyond science.

To this day, we don't really know how radio works, this is why we ALWAYS
throw in the term "THEORY!"
As, like God, we have NEVER seen an electron move through a wire either!
And, certainly, radio waves transversing the ether cannot be photographed!

Hi Jim,

That is simply repetition. The extension of copyright makes that
moot. Can you name a single Disney product with copyright that was
not licensed as a trademark right? No one is seriously interested in
Little Mermaid knock-offs but the Chinese. And how many dozen are
Disney going to sell to Chinese at $20 a pop when they can only afford
25 cents?

When the capitalists go into China with Hammer and Tong over copyright
issues, they are not selling anything. And since the introduction of
Linux as a substantial option, the Chinese have shown even less
interest in M$. There's the payoff of investments in Hammer and Tongs
on a sliding scale.

>> Really, the laws are manifestly and explicitly for

This lies somewhere between misty-eyed dreaming and the soft-porn of
industry pleas. There is absolutely no grant nor entitlement, much
less funding that is vested into R&D by the government's supporting
monopoly. Copyrights and Patents are boldfacedly proclaimed as rights
of enforcement ONLY. No R&D lab I've been in had a legal department,
and most companies that did have a legal department, bought their R&D
and simply did the marketing. If ever there was a case study of this,
it is M$. Chairman Bill's dad was NOT a mathematician NOR a
scientist, he was a Lawyer. He couldn't care less about copyright of
DOS1 because by the time any issue made its way through the courts, no
one would be using it.

Can you name the writer of DOS1? So much the value of copyright for a
trillion dollar industry.

An entrepreneur is the other guy with the money, not the one with the
intellectual property. I've pitched against more than $100Million
worth of these types, and most of them would stare daggers at you if
you uttered you had Patent pending. They know how to do that
themselves, and they certainly don't want competition seeing their

names as assignees in public records.

Jim, you got any of your own patents? Ever copyright any substantial work? How much did it tilt the balance ledger? There's reality.

I would not call evolution psuedo-science. It is just that there is
not enough data to prove or disprove the whole of the theory. The all
encompassing beginning from primodial ooze to modern man has holes in
the evidence. Because t here is holes does not make it psuedo-science.
So science must have faith that an answer is out there yet to be
found.

Hi All,

Now a quote from IBM (today, just as M$ quote was from today):

"Earlier this year, I.B.M. made a broad gesture toward what it
called a new era in how it controls intellectual property. It
announced in January that it would make 500 patents - mainly for
software code that manages electronic commerce, storage, image
processing, data handling and Internet communications - freely
available to others.

"And it pledged that more such moves would follow.

"This month, the company said that all of its future patent
contributions to the largest standards group for electronic
commerce on the Web, the Organization for the Advancement of
Structured Information Standards, would be free.

"I.B.M. is at the forefront, but companies in industry after
industry are also reconsidering their strategies on intellectual
property: What do you share? What do you keep proprietary?"

In today's marketplace, the pampered notions and dreams spun into
vague platitudes about protection are no defense to global cut-throat
capitalism.

These recent events throws the musty notion of patents being necessary
to support R&D into a cocked hat.

Franklin pointed out these false illusions long ago.

Hi Bob,

I dare say, if I paid attention to that (and I do, as it is part of my
work), that I would not find you or Jim's name there.

Ever see a copyright notice on a TV scroll? The more important mark
is the Screen Writer Guild's registration number. It's been 25 years,
but I've done this too.

You are underhanded, subversive, and your manner is below one of minimal human behavior--but I am positive--others have told you this--and obviously with little affect...
Attacking me certainly does NOT endear your person to me. I am sure that other thinking individuals recognise you for what you are and fear any exchange with you, do you like to live in isolation?
What is it that you have found in my posts which you fear and are attempting to divert attention away from? What has endangered you to the point of reducing yourself to a such a level as to make a "gutter attack" on anothers character?
Not only your lack of education and proper upbringing is showing--your very lack of character is SCREAMING in agony!

John

I have a BSEE and have worked in data communications for 23 yrs. and
that arguement does not hold water. Every aspect of radio can be
defined mathematically and adheres to well defined and well known laws
of physics.

Not so. Light is electromagnetic energy the same as radio waves and we
see light. Radio waves while unseen there pressence can be measured,
quantified as to power density and even measured as to how fast they
waves travel through different mediums.

It is with great misgivings that I am about to sell my
precious tower.

I am moving and also getting older and not going to put up
the tower at he new location.

I have a Telex 55 foot, fold-over, MOTORIZED,
self-supporting tower that is in excellent shape. This is a
SERIOUSLY HEAVY-DUTY TOWER.

This has a commercially built rotor control box that
controls a prop pitch motor that would turn a tank. The
prop-pitch motor is included and already mounted. For a few
bucks more, I will include the t-6061 mast and even a
fiberglass cross-mast.

This jewel is in my backyard and is currently up.

After I take it down, it will be ready to put up and get on
the air. I have everything with it including the in-shack
control box (HAM_M).

I NEED TO DETERMINE if anyone is seriously interested in
this because I have other things that I need to do rather
than take down a tower that there is not a serious prospect
for.

The tower is in Houston, Texas but is well worth a drive to
Texas

I am expecting to offer this for around $2500.00 FIRM.

Thanks

The folks who keep measuring those signals do so at the same place year after year.
Others keep building skyscrapers all around their hamshack, thus blocking the signals.
The signals fading from the shortwave bands is from the perspective of a receiver being slowly shielded.

Thanks Tom (& everybody else). The problem is that I'm planing on
having an 8' two section whip on the top that will power extend &
retract through the loading coil into the bottom mast.

Why?

Call it a combination of lazyness & a prepondarence towards low
ceilings in parking garages. Also (bonus), with the coil retracted
I'll be able to vary the height of the whip for the upper bands.

So what I was really looking (hoping) for is a black coating that
maintains electrical contact between the inner & outer whip sections
as one slides in & out of the other.

Don't look like I'm gonna get it :(.

Maybe it would be easier just to build a test range insted :).

H.

Has anyone taken a look at this antenna? I heard the designer on 75 last night working a CT0, he says his is 18 foot in diameter. His buddy was running a 6 foot version and 200 watts and worked the DX as well. He claims that it is a "minium reactance antenna" thus the name.

No, but as an advertising copywriter for much of my life, a lot of my
work was copyrighted -- not that that had anything to do with how much
I was paid, but I did okay.

631. Re: THE DATABASE...

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-12 01:24:48 UTC
From: John Smith <assemblywizard@gmail.com>
Message-ID: <DrF6e.105$Hu3.2220157@news.sisna.com>
Source record: 79209

I am just in the first stages of investigating this database myself. I am
not positive if I am interpreting the results correctly.
For example, I plugged Terman, Frederick, here is the result:

1. Registration Number: RE-187-468
Title: Electronic and radio engineering. By acFrederick E. Terman.
Edition: 4th ed.
Claimant: Frederick E. Terman (A)
Effective Registration Date: 2Dec83
Original Registration Date: 6Sep55;
Original Registration Number: A203084.
Original Class: A
Claim Limit: NEW MATTER: "revisions and new material."

I am guessing, but this seems to confirm the materials' copyright expired on
12/2/83 and there was no renewal and it now lies in the realm of public
domain--but am looking how to confirm this. I can find no other mention of
this work in the database...
Perhaps others can provide their knowledge/observations?

Regards,
John

I am only guessing, but there isn't a backpack/portable version of that
antenna available, is there?
And, I just looked at my car, where would I mount that?
Or, is that the kids playhouse, and it obscures the view of the antenna?
<grin>

No, stike that, looks like it was renewed... there are two registration
numbers... I am looking for now for some known works which have been
renewed, that I can check against--I expected this info to be more
organized...

How is it a failed argument to expect people to post discussion to the
appropriate newsgroup? None of this has anything The Simpsons, football,
or any of the other newsgroups it was crossposted to. Post your replies
to one of the religion newsgroups where they belong.

Unfortunately, we're stuck with a legislature composed of
lawyers who, when reminded that copyright was to be "for a limited
period" can, with a sraight face (and bulging pockets) say, "One
thousand years is a limit, is it not?"

There are several websites addressing copyright. Here in the US, copyrights
before 1923 are indeed expired. Some copyrights after this date are also
expired depending on renewal status at the times of various copyright law
changes but that gets a little complicated. No they cannot publish the
material as their own as that is plagiarism but they can publish it without
permission of the original copyright holder and do not have to pay anyone
for the right to print it. When a publishing house prints a new edition of
"Moby Dick", all the money goes to the publishing house. None goes to the
author's estate or heirs.

Has anyone done any testing (RF resistance) on squirting some NOALOX
compound (or other anti-corrosion sealants) between the aluminum
elements and scrubbing them clean to remove the oxide film before
bolting them together? Should help a lot, especially along the coast.

Works great on AL power wire at 60Hz...

>Boonton 250 RX meter and an H-P gray HP 250 RX meter out in my storage
>building.

Another rec.crafts.metalworking crosspost kibbitz: Double check
that - they could have been owned for a while, but it's far more
likely H-P ordered some made by Boonton in gray cases with the H-P
name on them. Far cheaper than H-P duplicating them from scratch, and
doing a total redesign so they don't infringe on any patents.

Happens all the time - for one example, Sears doesn't build power or
hand tools themselves, but they have the OEM suppliers put their name
on tons of them. Sometimes they're customer specific designs, others
are only 'badge engineered' from an existing design and change the
plastic feedstock color in the case molding machine.

In the past I've saved an average 20% by going to the OEM (like
Skil-Bosch) for parts when you can identify them, rather than the
Sears Parts Center.

I got creative and violated the EZNEC rules. The result was an
omnidirectional antenna with 30 dBi gain that cannot possibly
exist in reality because it violates the conservation of energy
principle.

But there is a grain of truth in what you say.

Calm down, bubbaboy. :-) a little touchy, aren't we ? I did not attach
you.
But you, in just a few lines, have managed to perform an attack of huge
porportion.
An attack not befitting a gentleman.
You should now voluntarily turn in your gentleman credentials immediately.
(But you can still go ahead and make that antenna).

The problem with aluminum at the coast isn't an oxide that has to be removed. It's just the opposite -- the problem is that salt water removes the oxide that needs to be kept intact. Aluminum is a very active metal, which oxidizes almost immediately on exposure to air. The oxide is a hard, non-porous ceramic which, after forming a very thin layer, prevents any further contact of the aluminum with air. The problem is that aluminum oxide is slightly soluble in salt water and other acids. So the oxide coating is removed by the salt water, exposing more aluminum to salt water and air, allowing it to corrode. It does help to coat metals with grease, but only because it prevents the salt water from contacting the metal or, in the case of aluminum, the oxide coating. But the last thing you want to do is intentionally remove the oxide coating.

Gets a "little complicated.." ??? Amen! The laws have been more like
"totally subverted" from their original intent.
Strange there is no way to search the database, specifically, for expired
copyrights! Huh, almost enough to trigger my "conspiracy theory"
tendencies! Of course, perhaps Micro$oft developed the database--that would
be one acceptable explaination...

Hi Jim,

Frankly I don't have a single thought about government in this issue.
Unless, of course, you are from the school of what's good for (fill in
the corporate blank) is good for America kind of government. I
thought that got gummed up in the tar pits years ago.

Actually, I correct myself again, it looks like Termans' book is expired
copyright, if you look closely at the post above and the field:
" Claim Limit: NEW MATTER: "revisions and new material." "
you will see that this entry is actually a NEW copyright work, and that the
copyright is limited to ONLY the "revisions and new material."
However, as this guy (corporation, company, business, individual, etc.) has
done, a person could duplicate the "original text" of Terman without
violation of copyright law, AND also tag on some "new revisions and new
material" just to obsfucate what has been done! and obtain a copyright on
the "revisions and new material"-- fooling some into believing the old text
was still copyrighted...
At least, from consulting with others who claim to be more familiar with
such, that is the conclusion I draw.
Anyone here with more information, or who can correct my mistaken
conclusion(s)?

Regards,
John

Hi Brett,

Read up on "Fair Use." Wholesale reproduction is not going to market
anywhere where it won't be perceived as just that. Further, it can't
economically compete with the used book trade in the marketplace.

Beyond that, extensive quotations for the purpose of bolstering
arguments or illustrating concepts will only act as a soporific.

More to your original question, the Government Printing Office has a
website and a search engine -- but it brings up only some rather
mundane papers when searching for "antennas"...

N8WWM and another individual have been harassing CB'ers
for 5 plus years now in Rec.Radio.CB. Sending threatening Emails, signing
you up for Spam, sending virus, false
accusation, vulgar language, making vulgar web pages all
this while changing screen nics to bypass filters so that you
don't have the chance to filter them out.
Rec.Radio.CB used to talk about radio both legal & illegal,
but these two people came on to the group both supporting
and condoning illegal activities, but found it was mush more
fun to harrass and flood the group with useless posts, sometimes 100 to 200
posts a day!
Being Steveo is close to these people, he's called them on
their offers of, "Go ahead, we invite you to show up". Well
Steveo did just that and the best they could do was peer out
the windows and door, to afraid to stop out into the street.

Landshark

Now watch the responses they throw out ;)

================================

Before anybody can get anything out of the Internet somebody has to be
paid to put it in.

Radio amateurs are but a small proportion of the world's population.
I'm for ever surprised at the quantity of information which is
availble.

Tthe big question mark hanging over 'information" is Reliability? Can
you believe it? Google is anything but the Bible. Much information is
from sources as trustworthy as where the weapons of mass destruction
came from.

But searching is a pleasant pastime, is it not? And it's seldom a
matter of life or death.

Reg, G4FGQ

Wouldn't it be easier to just use a single
higher gain yagi? I'm not sure of the gain of
a "moxon" antenna, but seems they were a
compromise reduced size, or wire X design???
Not sure...I'd have to look into moxon antennas..
I use just a single 3 el NBS yagi and get
about 9.4 dbi gain or so. "free space" MK

Not only will having the base grounded make it more
stable, it also provides a much better return to earth if
you take a spark. Providing you ground the base well,
anyway... It acts as a lightning rod.
So you want to ground it like one.
You could make a hinge. Some use a tower section,
and adapt the holes, thrust bearings, etc to fit a mast.
You could also weld a heavy plate, etc, with a short
pipe stub to fit masts into. That could be hinged to a base
plate. I have a tower that is set up this way. It's tilt over at
the base, and also crank up...The base and hinge part
was made down at the shipyard using ship steel.
Very heavy duty...The pieces were cut out on a CRC
plasma table that they cut pieces of ship steel on...
The thing will stand up by itself in the middle of a field,
even with the tower raised, and the beam on it, with no guys...
But I guy it to be safe...I've been taking it to field days the
last few years..I've got "drive on" mast holders that were
made from the same heavy stuff. You could rig one of those
to hinge on a baseplate no problem. MK

Indeed. Try creating something of your own, and see how you feel about
somebody coming along and claiming the product of your effort for
themselves. If you can't comprehend that, then consider what it might
be like for someone to put your house in their name and then sell it.
If you can't get a feel for that, then imagine somebody coming along and
taking food our of your child's mouth because it's 'the people's food'
and everybody has a right to eat it.

Thanks for the tip! I thought about the 3 el NBS and
other designs but when I found plans at Cebik's
site for a **wire** Moxon, I was sold!

http://www.cebik.com/moxon/6m.html

(near the end of the page)

One trip to the hardware store:

2x8' Sch 40 1/2" PVC to form an "X" shape
1x1' Sch 40 1-1/2" PVC to bind the X
2x hose clamps to clamp the 1-1/2" PVC to my mast
19' 14g stranded wire for the antenna itself
Electrical tape, string, solder

I had the coax, string, solder & SO-239 to connect
the antenna to the coax on hand. Total cost from the
hardware store - $11.95

Now all I need is a band opening....hihi

That isn't necessarily due to any intent to obfuscate the situation.

US Copyright law says that if a work is in the public domain, the work
itself cannot be re-copyrighted. However, anyone can then create a
"derivative work", using the public-domain work as starting material,
and then copyright the resulting derivative work. If, for example,
you start with a black&white news photo which is in the public domain,
do some simple Photoshop or GIMP processing on it to colorize it (or
include it in a collage or photomontage) you can copyright your own
version of the photo. The original photo remains in the public
domain, while your version (with your creative effort) is now
copyrighted.

As another analogy, one could take the text of Moby Dick (in the
public domain and freely available on the Net) and run it through a
creatively-programmed "English to Valley-speak" or "English to Jive"
translation filter. The result would probably be copyrightable, if
rather silly.

There are, I believe, various legal rules-of-thumb to determine
whether the creative effort involved in making a derivative work is
sufficient to support its being placed under a new copyright.

It's very possible (almost certain, in fact) that the 1983 version of
Terman involved sufficient creative effort to revise and enhance the
text of the 1955 edition, to justify the new version having its own
copyright.

The easiest way I found to figure this out, is to start from the
basic Ohm's Law formula for two impedances in parallel:

Zt = (Z1)(Z2) / (Z1 + Z2)

Let Z1 be a purely real impedance (Rp + j0) and Z2 be a purely
imaginary impedance (0 + jXp) and calculate from there.

It was a fun bit of scratchpad-and-pencil-in-the-afternoon to start at
Ohm's Law, and end up with a pretty decent understanding of how L- and
T-match antenna tuners (transmatches for the purist) actually do what
they do.

The firewall at the GED office doesn't allow access
to Google. I was using the Netscape search engine
searching for "series to parallel impedance conversion"
which yielded http://www.cebik.com/gup/gup23.html. Those
equations are NOT on that page.

Might also check out address below for a moxon calculator- just
enter frequency. and it will also write .ez files, and for NEC
for the above. If you use eznec, or nec, this will allow you
to display the pattern of the antenna. It is also a downloadable
program, in .zip format. As info, Jim NN7K

Knowing whether or not you had a camper shell on that pickup would be
useful as (IMHO) a point just behind the cab would be the best place to
locate an HF antenna.

Hi Jim,

Well, you need to have www.imdb.com update their credits list:
http://www.imdb.com/title/tt0116313/fullcredits
I don't see your name in the 60-odd performers credited, nor do I see
it in the list of 120-odd crew and other artists. The closest match
against your name is Paul Kelly. There is only one Jim Kelley (with
all variant spellings considered) in their database:
http://www.imdb.com/name/nm0445920/
he died 72 years ago. However, there are 430 Kelley/Kelly entries if
you were not working under the name Jim/James:
http://www.imdb.com/find?q=kelley;tt=on;nm=on;mx=20

Could it be that you supplied the working title against which "The
First Wives Club" was released makes some difference? Or is this more
an issue of "you" having credit is a metaphor for a company name you
worked with or owned?

To lighten up, as you once advised me, when I was mixing a radio play
that I and my partner wrote, I boosted the mike levels when my name
was given credit.

The producer caught that and mixed it back down before broadcast. :-)

Here is how I mount my screwdriver, a 4 foot Tarheel with a 5 foot whip.
I used a 103" whip for a while, but it hit overpasses on interstate
highways.
The truck is a Dodge Durango. I installed a ball mount on the right rear
where I could get at the backside of the mount from inside the truck. Turns
out there's a vent in the plastic interior that's easy to cut away.
To stabilize the screwdriver I mounted a U-bolt directly into the truck body
with large washers and a PVC ring on the antenna. Tightening the U-bolt
about the PVC ring pins the antenna to the truck.
After finding resonance with an antenna analyzer, the impedance on 40 turned
out to be 20 ohms. I built a toroidal autoformer to match it to the 50 ohms
of the TS480HX. I also have a BIG Hi-Q with a cap hat for 160 on up.
On the left side of the truck is a Hi-Q "shortie" (I forget the model) for 6
on down just on a ball mount and no matching network. I'm on the Spiderweb
Net often with this rig. (14.347 @1230Z daily).

I know I married this truck when I drilled holes in it (An NMO on the roof,
too.) At 96,000 miles I still have the original brakes and tires. There
have been no repairs. BTW the radio's mounted in the back, feedline's about
a foot to the big screwdriver, about three feet to the little Hi-Q.

Nice job! Most guys don't want a 1 3/8 hole in their cab body! Just in case, though, they DO make rubber hole plugs for that and its associated 3 1/4 inch holes... in case you ever do turn it in for a new model.

Dear Mr. Busch WA3MOJ, I ask that you please stop changing your
screen nics to by pass newsfilters, per you're ISP's TOS you are in clear
violation doing that just to harrass me.
You have changed you screen nics 3 times this week alone,
with none of them to begin with as valid, so again, please stop
this.

Richard:

In the back of my mind I am picturing a library of collected works with
expired copyright/public domain/orphaned works...
Something akin to the gutenberg project, but not on such a large scale; but,
a technical library is what I imagine...
Surely there are more than just me which can see such a tool as a noble and
just cause.

Companies, corps, etc. I have worked for usually have a policy and make
known basic facts about "fair use" and how you can duplicate limited
portions as an aid to ones' own speechs, documents, study materials,
etc.--when giving the author(s) full credit...
I wish I had paid more attention, I tend to just digest material and
"reguritate" it in my own words and suppling my own pictures, charts,
diagrams, etc.-- that itself is so easy--why bother stealing anothers words?

However, a library of expired copyrights is really a tribute to the
individual(s) who have created the work(s), and is an important effort at
passing on learning, knowledge and wisdom--as such, its' very nature stands
alone as nobel cause...

Regards,
John

KWAAANNNNG! (or other odd sound as you see fit)

Yes indeed, it just may drive software companies to adopt a different
paradigm. It is about time!

Right now, it would seem we need a new improved operating system every
two years, according to the comapnies that make such things.

We need a "new improved" word processing software, laden with "features
that no one will use, according to those same companies.

When in fact, what I want is an operating system that simply works, and
allows me to see my files and work with them.

And programs that work. Which we will not see until we DON'T have a new
operating system every two years.

My post was simply abreviated, but points out:
1) It is possible to "create" a "new" work from an expired-existing one.
2) Care should be taken NOT to confuse the fact that the actual copyright on the EXISTING work has expired and the "author" actually has NO copyright on what was/is the existing material in question (may be freely copied, duplicated and disseminated as desired.)
3) Some may find a way to use this as a SCAM; also, those who have not examined the workings of this system closely can be easily deceived into what, exactly, the material is they are receiving.

It is also interesting to note that this is a work from 1955 with an expired copyright. I think one is likely to find that technical material is more quicker to be come dated and orphaned (becomes expired copyright) than most all other books, documents, music, pics, etc...

John

Hi Fred,

A simple glance at the SWR chart reveals it is in fact a Maximally
Reactive Antenna - at least the initials are preserved.

I'm having a hard time seeing the "minimal reactance" part of this
design. Looking at the plot of S11 it looks pretty much like any
other antenna with a single resonance.

It has "minimal" reactance at resonance and is highly reactive
elsewhere.

A conventional monopole, resonant at about 7 MHz, would completely circle the Smith Chart for almost two complete revolutions from 1.8 to 30 MHz. I suppose that is what is meant by "MRA". Apart from that it would be interesting to know the precise structure details to attempt a NEC model. It looks suspiciously like the CFA class of antennas.

Thanks for the reply Richard...

He and his cohart were in the DX window on 75 working a CT0, his buddy had a 6 foot version and both got good reports. The large (18 foot) was running 1500 watts. The smaller one was running 200 watts. As to band conditions, I later worked an EA with a 5/9+ running 100 watts to a G5RV. I was hoping one of the EZNEC Gurus would take a look and give us the skinny.

When I looked at the photo, I had deja vu of a CFA.

Hi Ken,

If you push more power through it.

Aside from that, how much better is better? If you start out with a
miserable quarterwave and replace it with a sterling (pun may be
intended) shorter antenna; then, yes, the shorter one "may" be better.

Why don't you first start by defining what efficiency your quarterwave
whip exhibits? You may be surprised how hard it is to "better."

I just ginned up a 5 foot tall antenna with 3.8 dBi gain. That's
half the height and considerably more gain than a 1/4WL whip.
With more time, I could do better.

707. 2m beam antenna with 45 degree coverage?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-13 18:24:41 UTC
From: Tony VE6MVP <tony@REMOVEve6mvp.com>
Message-ID: <akoq515ah8koj6dphhmvh9rvkqeg1lrsfb@4ax.com>
Source record: 79172

Folks

I may be spending a significant amount of time in a small village about 30 miles away from the "big city". I'd like to be able to participate in the 2m repeaters, I suspect almost all of the repeaters would be in an arc in a 45 degree angle from that small town. Thus I'm thinking a beam antenna with a 45 degree coverage would work well for me. I could then put it in a fixed location pointing to the big city. It also wouldn't have to be that high up.

Ideally this would also cover 70 cm as well. Do such exist?

Or would a 8' omni directional vertical antenna on the end of the peak of the house also give me decent coverage for the 30 miles?

Part of this depends of course if the village is on the back side of some hills which is quite possible.

Tony

I could probably park my truck out in front of his
house, and do the same thing with my mobile
antenna...My mobile often outperforms my 35-40
ft high dipoles to DX on the lower bands....
To me, it seems to be a very ugly version of a
short top loaded monopole. Nothing more, or
less really....1500 w? He *should* be working dx,
or something is kuput....I work DX mobile with 100w
no problemo. That the "MRA junior" is only 200w doesn't
mean too much to me. He's still twice what I run...
If I were to run a MRA, I would at least install a hot tub
or spa in the middle...Add cup holders...Seats around
the outer section...etc...Shrubbery around the outside to
keep the old lady happy....Hell, with a used JATO engine,
you could probably take a trip in that thing...
I bet it would show on radar, until you ran into the underbelly
of that passing 737-700 that happened to be flying over the
house at the same time...:(Ouch....Can we spell headache?

709. Please some advice

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-13 18:51:06 UTC
From: EpsilonRho <EpsilonRho@nospam.ooo>
Message-ID: <uSd7e.1286$J12.160@newssvr14.news.prodigy.com>
Source record: 79174

I live in a area where the radio FM signals from various broadcasts are quite weakly and coming from different directions. I was thinking to put on my roof an omnidirectional vertical coaxial FM antenna (two elements of 1/4 wavelength), but I think that the losses through the coax cable could be substantial. In order to alleviate this problem, I could put an in-line amplifier just under the antenna. As an alternative, would be possible to install multiple vertical coaxial antennas, perhaps 3 of them, forming a triangle and connect them in parallel? But by doing, the characteristic impedance would drop by a factor of three. Is perhaps a three way splitter more suitable to maintain the correct output impedance? At what distance should I install the antennas from each other to assure omnidirectionality? I am not very knowledgeable about antennas, having just a degree in power generation.
Many thanks for you help & advice.
Gene

It looks to me as if this is a member of the "Super C" antenna...
short, relatively low radiation resistance, and a lot of top-loading
capacitance.

There's an article or two in one of the early ARRL Antenna Compendium
collections (#1 or #2) which analyzes the "Super C" approach, compared
to a short vertical with a more traditional capacity hat made of
straight wires. The analysis seemed to add up to "Probably not worth
the trouble and money", as a similar efficiency can be achieved more
easily and less expensively with the traditional approach. There's a
lot of metal in the MRA, and at the price of aluminum this month I
doubt it's a project I'd start.

Hi Gene,

This has a good chance of working, even for a simple single element
antenna.

> but I think that the losses through the coax cable could be
>substantial.

You don't explain why, and an external antenna, up high can make a big
difference.

>In order to alleviate this problem, I could put an in-line
>amplifier just under the antenna.

This is also a good idea especially if the simple antenna does not
work well. More antennas probably will not give you as much gain as
the amplifier so if the simple antenna does not work, go straight for
an amplifier.

Hi Tony,

If it doesn't, you have to consider that your choice for a beam (make
sure you align it vertical as most repeaters will be vertical) with
wide beamwidth and dual band capacity would probably describe a simple
log periodic. One thing to consider, if this "big" city is 30 miles
away, and spans 45 degrees, that is indeed a very "big" city.

>Part of this depends of course if the village is on the back side of
>some hills which is quite possible.

Do a survey in the neighborhood with a handheld and see how hard that
is. Then repeat the survey with a small ground plane connected to the
handheld and hike the antenna 5' up on a broom stick.

The real challenge is how high are the repeater antennas? I can hit
my buddy's repeater here in the basement with a half watt (I'm not
readable but I can trigger the courtesy tone), and I'm behind the brow
of a nearby hill.

Well some of the repeaters are at either ends of the city. But it's
more like 30 degrees.

Good suggestion. I'll do that the next time I'm in the area.. Wonder
what the folks in that village will think of me? Do you think I
should wear those big head phones too? <smile>

And when I think about it if I can make it to the repeaters with my
mobile antenna then a house vertical whip will be significantly
better. Yeah, the more I think about it I should do some more
testing before I posted.

Y'know, I had *started* to add a paragraph to my posting suggesting
that this antenna could be disconnected from its feedline and used as
a jungle gym, but decided that it was a trifle irresponsible to do so.
Too much potentially-sharp metal edges to have around the kiddies, and
there's always that chance that Dad might accidentally key up QRO at
the wrong moment. "Honey, I smoked the kids!"

I am sure you did Cecil, however I understood the question to be a shorter single element mobile antenna. I suspect he was looking at the shorter loaded antennas with gains far in excess of your paltry 3.8 dBi. See any CB site for examples.

One loaded antenna is touted as having 7.2 dB gain.
but then again it was a "super coil" rated for 10,000 watts.

Other than that, "The angels have left the pinhead".

Well, that's why I asked for a definition of "better".
And he didn't say a "single element" was better so
a 10-element beam might be the way to go. :-)

A balanced fractal top hat cannot be beat!!! :-)
That's one of the things that fractals are good at.

Sorry - let me elaborate *why* I posted the question.

I wanted to know if it was possible for any single mobile
antenna less than a 1/4 wave could outperform a 10m 1/4
wave whip. Like for example a loaded 5/8 wave whip.

As I understand it no whip less in size than a 1/4 wave
can be more efficiant than it's larger cousin due to resisitave
losses in the loading coil.

Right or wrong? Long answer is OK. :-)

Hi All,

I pondered the page above, and then the website and chose a page at
random (well, directed drift perhaps given the link topic of Top Hat):
http://www.smeter.net/antennas/tophat2.php
and found:
Performance of Short, Vertical, Top-Capacitance-Loaded Antennas
Author: R.J.Edwards G4FGQ ï¿½ 3rd October 2002

Funny, Reg, I thought you would have chosen to publish at
www.antenna.load.indicator.net instead. :-)

A loading coil does not make an antenna longer. It simply cancels the capacitive reactance of a short radiator.

A 5/8 wave is using the associated coil to match the impedance. Ergo if it is 5/8 it can't be shorter than a 1/4 wave.

Cecil's 10 element mobile 10 meter beam aside, the answer is still NO to your original question.

The other way to cancel the capacitive reactance of course, is to make
the antenna longer.

If the quarter-wave whip is made of ss, then you can make a better antenna
by plating it with copper - or - gold - etc - or replace it with a better
conductor. Then use a better transmission line. Then park the vehicle on top
of a very high mountain to work dx.
so, ... conditionally - yes.

Would you care to postulate the dB increase by plating with copper or gold?

Hi Fred,

Could be up to 3 or more dB over an unspecified quarterwave efficiency
(ï¿½3dB, offer void where permitted by law).

Try 2 or 3 rabbit-ear antennas. Easy to adjust, etc - up in the attic.
use 300-ohm cable (its low loss).
use splitters to fan-out the 300-ohm cable from the radio to the several
antennas.
If this works, please apply for a patent in my name and copyright the
instructions.

:-)

There is only one SET of traps per element on the TA-33 series of antenna.

Ten meters the traps act as decoupling.
The fifteen and twenty windings are internal, with the outside aluminum can
forming the capacitator.

In other words a total of six traps for the three element tri-bander.

Hope that helps, considering all the smart arsed comments it should.

Dan/W4NTI

30 miles ain't that far. I have no problem hitting repeaters from 40 miles
out (mobile), but our repeaters are on towers.
Put yourself a 5/8-wave mobile mag-mount on the car and drive out to the
village while the repeater is in use. Make note of 'quiet zones' (bad
reception areas). Avoid those areas when the time comes to set up there.
You should have a better idea after your day trip, about the gain you may
need to reach and hear the repeaters.
Usually, if you can hear a repeater, you can talk to it.

Depends on the customer. If the customer is really building a CB antenna,
then I could claim 12 db gain.
But to you folks, I wouild say the gain is marginal at best. But it would be
a "better" antenna.
Wouldn't you say a gold-plated antenna is better than a stainless steel
antenna? After all, it cost a bunch more and the mfgr claims 12 db gain.
--- the part about parking on top of a mountain is the best part of the
recipe. - and gives the most gain. (height-gain).

It was in comparison to a stainless steel whip. let me be more specific. The coating of either copper or gold (your choice) of up to 50 mils over the stainless. Any other plating to allow the proper plating of the copper or gold shall be limited to 5 mils and materials normally used to facilate plating over SS.

Compare in dB SS whip before plating to SS whip after plating. I am sure I have left out something else that may generate yet another waltz on the head of the pin.

tony
to answer your question
any 3 to 5 element yagi would do what you wish beamwidth that is
cuchcraft makes a dual band 3 element and a 5element yagi neither one
costs to much
put either one on a 20ft pole and you should be able to hit anything you
wish
also a Comet GP9 dual band vertical at the same hieght would do you well too
but a little more costly
good luck

for what bands dave?
for HF RG213 would do you nicely
but if your doing VHF/UHF you really need a good coax like 9913F or
LMR400 they have a buryflex just dont recall the model number
keep in mind at VHF freqs 100 or more you really start to lose a lot of
RF with cheap coax
RG213 at 400mhz @100ft is more than 9db of loss which is a lot
good luck

Speaking of skin effect, consider a threaded rod on
edge with all those hills and valleys.

```
/\/\/\/\/\/\/\/\/\/\
|\ \ \ \ \ \ \ \ \ \ |
/\/\/\/\/\/\/\/\/\/\
```

Does skin effect force the RF to flow up and down
the hills and valleys thus increasing the VF of
the threaded rod?

In a related fashion, if you have a sort of reverse copperweld, that is to say copper wire plated with steel, does the skin effect mean the RF is confined to the steel?

Since skin effect has to stop somewhere - I mean insulated wire doesn't have the RF try to run on the insulation, at what point does skin effect stop, resistance of the outer part of the wire as a factor?

Does skin effect and insulation have any relationship with velocity factor?

Or have I opened my mouth and removed all doubt as the old saying about stupidity goes? 8^)

I don't mind putting holes in my cars/trucks. I keep 'em so long that, by
the time antennas would be an issue, the car is worth about $500. So I don't
mind and it don't matter! :)

Better check your numbers again. RG213 is more like 4.7 dB/100'
@400MHz

Yes it does.

Skin depth in metals at HF is only a very few thousandths of an inch, and less. The current has nowhere else to go except up, over, and down the humps of the screw threads.

But in practice, the RF resistance is not increased very much because the diameter of a screw is usually very much greater than the diameter of, say, an antenna wire, and so its resistance is already quite low before it is threaded.

Reg.

755. 1000 watt HF amplifier: what about nearby antennas?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-14 16:15:11 UTC
From: Pat <phoneguy99.delete@delete.sympatico.ca>
Message-ID: <wFw7e.5148$MZ2.779620@news20.bellglobal.com>
Source record: 79120

I just bought an Icom PW-1 (1kW) amplifier. My concern is whether or not I could potentially burn out the front end of other receivers attached to nearby antennas. My tower clears the roof line of the house by about 10'. The 6 band HF beam is 1' above the thrust bearing (top of tower), and approximately 8' above the beam is the triband vertical (at the very top of the mast.) That said, there will definitely be a significant RF field above and below the beam, as well as to the obvious front and back of the beam.

So, is there a danger of inducing destructive voltages to the vertical above? What about other antennas on my roof near the tower?

My beam is well above the roof line, but as I have two tripods on the roof, each with assorted verticals and beams {6m - 70cm LogP, two discones, a 902 yagi, and 902 vertical, and a 220MHz vertical.) These are each 25 to 30 feet away from the HF beam. There's also a distorted G5RV (aka: has a 90 degree turn near the end of the long leg as to stay on the property) running off the roof to some trees along the back fence.

So you see my concern about having a 1KW RF source in proximity to all the other antennas. Any other kilowatters out there with some experience or advice to share?

'73,
Pat, VE3PMK

A Steel over Copper conductor -

At very high frequencies current will flow only on the outer surface of the steel according to the conductivity of steel.

As frequency decreases, current will flow in the copper only when skin depth in the steel is greater than the thickness of the steel covering.

As frequency decreases further current will begin to flow deeper in the copper according to the conductivity of copper.

The resulting resistance of the composite structure is the resistance of the steel layer in parallel with the resistance of the layer of copper, taking the currents flowing in each layer into account.

But at HF, unless the steel layer is microscopically thin, the resulting resistance will be practically the same as that of a solid steel conductor.

Reg, G4FGQ

Imagine a rod with 60 degree notches cut out of it
such that the RF path is twice as long as is the rod.
VF = 0.5? 1/4WL vertical = 117/F? 75m vertical = 31ft?

I used to bury RG-213. It'll last longer if you slide it into some cheap garden hose before burying. Scrap and second hand hardline is a better bet and is really long-lasting. I got some new scrap pieces of over 100' of 1/2" Andrew for free and bought 200' of used 7/8" Andrew hardline with connectors locally for $50. It replaced 1/2" stuff at VHF/UHF. The difference is noticeable.

Check with your local broadcast stations and 2-way radio shops.

It won't melt them even if you connect the antennas together with wire.

Thanks to all for your input, the installation will be for HF and
100watts or less so I've decided to go with some direct bury RG6 which I
can get from the Local cable company at a good price. Should work ok.

So you see my concern about having a 1KW RF source in proximity to all
the
other antennas. Any other kilowatters out there with some experience or
advice to share?

I've wondered the same, and have in fact heard of people
frying the front ends of radios from that...But I think it depends
on the radio, the difference in freq's, etc...I've had two meter
rigs hooked to ground planes, and yagis, that are on the same
mast as my dipoles, and I never had any trouble...But thats not
to say someone else could have a problem. The earlier IC -706's
had an issue with trace burning, or something along those lines,
from the RF from one band, causing a problem through the other
side of the radio. "HF". I think it was the VHF melting the HF trace,
but not sure...But they fixed it on later models...I *think* mine is
one
of the later "fixed" ones...I've never had that problem..Anyway, if
it really made me nervous, I'd unhook the other radio. I did that
sometimes, when I was really browning the food on HF. Even if in
a semi null, the FS is going to be high, at that short distance. MK

>on the radio, the difference in freq's, etc...

I just read an article in the ARRL Antenna Compendium #3 by a guy who
used to live (and work HF) on the grounds of a big AM/shortwave
broadcasting farm in Quito. The RF field strengths were several times
what the FCC now allows for human exposure.

He had some serious RFI problems. One amateur near him put up a
20-meter quad, hooked it up, and smoke came out of the receiver... it
burned the coils. He put up a 40-meter dipole, and found that it
could light up a 100-watt bulb!

His article has a number of suggestions for people suffering
high-energy RFI problems... might be worth your reading.

For the situation where the high-power source and the vulnerable
equipment are on greatly different bands (e.g. kilowatt HF and a
2-meter antenna) I think you're at substantially lower risk. It might
be worth your while to gin up a simple high-pass filter for the
two-meter gear. A quickie approach would be to buy a commercial
2-meter/HF diplexor, and leave the HF side unconnected (or terminate
it in a 50-ohm dummy load). Maybe add some ferrite chokes to your
2-meter feedline, just to discourage it from acting as an HF antenna
and bringing RF back into the shack on its braid.

I just drilled a bunch in one of mine...Typical ball mount, with
four holes total. "One big"...And being the cab is double wall,
I also had to drill holes inside the cab wall also.. That one is
almost at roof top level, at the base...:) I have a camper on that
truck, "actually both of mine do", and installing an antenna is a
PIA. I'm not overly keen on bumper mounts, except that they do
often allow a long lower mast..The hang is much of that lower mast
is up against my tailgate, and camper back. Not really good...
I decided I only live once, and go for broke.
It's up on the cab, on the drivers side pillar behind my head.
The higher bands work a good bit better there, than the bumper...
It's a tree whacker though...Thats why I always mount on the drivers
side...You have a better chance of getting the "gap" between branches,
when driving down a street. So far, with the little amount I've used
it, it seems to be browning the food. I was on 75m one night, and got
a 20 over 9 from one guy about 200 miles away, with my usual 100w.
Yes, s meter reading doesn't really mean much, but it does indicate
it's
workin...It wasn't that late in the evening either, which was a good
sign.
Usually, for a mobile on 75m, the later it gets, the better in general.

Long haul for sure...In the early PM, when it's mainly up/down NVIS,
a mobile can be the pits compared to the dipoles...But they usually
wake up later when the lower angles started working better..

Or an SWR meter....:/ With that much loss, even a dead short
would probably look acceptable...
As far as 213 coax, it *is * a direct bury coax. You can bury it
no problem. Rg-6 is a 75 ohm coax used for TV/Cable.
It will work, but it would be better to use a 50 ohm line, being
you have a 50 ohm rig...Will cause you appx a 1.4 to 1 mismatch,
with is no big deal really...It will reduce your "usable" bandwidth
though...I use 213 on VHF for short runs...Some loss, but not
enough to kill you...None of my coax runs are over 50 feet..MK

I have about 175 ft of Davis "Direct Bury" Low Loss 9914F total at my station. It is superb 50 ohm low loss coax that requires no "garden hose" or "pvc" tubing. Just slit the soil or trench it and lay the coax in. At HF frequencies it is virtually lossless. It is within .1db in loss as compared to 9913 plus it is very flexible and can be used on rotators directly where 9913 cannot. And moreover 9913 cannot be buried directly.

IMHO it is the best coax to use.

Back in the '50's, 75 ohm line matched the alleged
feedpoint impedance of a 1/2WL dipole and nobody
used an SWR meter anyway. All we ever monitored was
grid current and plate current. :-)

Hi Pat, short answer is yes, especially for the other shortwave radios.
Invest in some coax switches to disconnect unused receivers.
VHF/UHF radios might be OK, but a bandpass filter would help to isolate
them.

Also, any RX that has diode protection in its front end will turn into a
great harmonic generator when blasted with a big antenna signal.

Cec, now I can see what you're getting at.

Firstly, wrong - the difference between a very efficient antenna and
a very efficient antenna is absolutely negligible and not worth the
extra labor involved.

Secondly, the expected 4-fold increase in loading inductance to tune
the antenna to one half of the original resonant frequency, as a
result of cutting threads or slots in the fat antenna rod, does not
and cannot occur.

But you win first prize for ingenuity. ;o)

I'd be a little wary of using RG-6. It is 75 ohm cable, will be quite a bit lossier than RG-213 or similar sized cable for your 100 foot run, even at HF generally has an aluminum shield. That means you'll likely have to use an "F" female to PL-259 adapter.

I've used the stuff for feeding a beverage receiving antenna for 80 and 160m but I wouldn't use it for much else.

Download Slackware Linux and spend the time to learn it, you will NOT be disappointed!
There maybe a "LUG" near you (Linux Users Group) they will be more than happy to help your learning curve--and from time to time they host "Install Fests." Just load up some old computer laying around (a 133 Mhz or better, and "better" I do recommend) and you will go home from the install fest with Linux on the machine!

Regards,
John

Well, perhaps you are correct... however, the Dead Sea Scrolls (some of them) were drafted within the lifetimes of individuals which were living during Jesus's lifetime--I would think it would have been hard to have fooled them--and they would have quickly pointed out that no such man had ever lived... Also, somewhere on the web I seen a page claiming that Jesus was actually mentioned in some ancient Roman records which have been recovered--I have not researched this... But, am always open to finding our more info on this subject, just have been doing other things--I will get around to it.
To me, I am amazed at the apparent lack of interest in the most important question which has ever existed--"Where did mankind come from?"
To me, people who do not constantly sift the sands of knowledge for clues are an enigma. As, they strike me as a man who has woken up in a strange land, not knowing his purpose or whence he came, with absolutely NO knowledge of his past--and simply picks up his life with NO knowledge of his past--and quite happily goes on about his business--even attempting to convince others that this is a sane pursuit!!!

Well, moisture and electrical conductors just cater to my paranoia's....

I encased my coax in underground PVC conduit, which I cemented all joints on, and then "air tested" (sealed the conduit ends and pressurized to 15 LBS and made sure there was no noticeable loss over a few days.)

I still worry about it--in the wee hours of the morning--when I can't sleep <grin>

The reason some people don't know for sure if they are going to Heaven when they die is because they just don't know.

The good news is that you can know for sure that you are going to Heaven which is described in the Holy Bible as a beautiful place with no death, sorrow, sickness or pain.

God tells us in the Holy Bible how simple it is to be saved so that we can live forever with Him in Heaven.

"For if you confess with your mouth Jesus is Lord and believe in your heart that God raised Him from the dead, you WILL BE SAVED." (Romans 10:9)

Over 2000 years ago God came from Heaven to earth in the person of Jesus Christ to shed His blood and die on a cross to pay our sin debt in full.

Jesus Christ was born in Israel supernaturally to a virgin Jewish woman named Mary and lived a sinless life for thirty-three years.

At the age of thirty-three Jesus was scourged and had a crown of thorns pressed onto His head then Jesus was crucified.

Three days after Jesus died on a cross and was placed in a grave Jesus rose from the dead as Jesus said would happen before Jesus died.

If someone tells you that they are going to die and in three days come back to life

again and it happens then this person must be the real deal.

Jesus Christ is the only person that ever lived a perfect sinless life.

This is why Jesus is able to cover our sins(misdeeds) with His own blood because Jesus is sinless.

The Holy Bible says, "In Him(Jesus) we have redemption through His blood, the forgiveness of sins..." (Ephesians 1:7)

If you would like God to forgive you of your past, present and future sins just ask Jesus Christ to be your Lord and Saviour.

It doesn't matter how old you are or how many bad things that you have done in your life including lying and stealing all the way up to murder.

Just pray the prayer below with your mouth and mean it from your heart and God will hear you and save you.

Dear Jesus Christ, I want to be saved so that I can have a home in Heaven with You when I die. I agree with You that I am a sinner. I believe that You love me and want to save me. I believe that You bled and died on the cross to pay the penalty for my sins and that You rose from the dead. Please forgive my sins and come into my heart and be my Lord and Saviour. Thanks Lord Jesus Christ for forgiving me and saving me through Your merciful grace. Amen.

Welcome to the family of God if you just allowed God to save you. Now you are a real Christian and you can know for sure that you will live in Heaven forever when this life comes to an end.

As a child of God we are to avoid sin(wrongdoing), but if you do sin the Holy Bible says, "My dear children, I write this to you so that you will not sin. But if anybody does sin, we have one who speaks to the Father in our defense Jesus

Christ, the Righteous One."

Those of you that have not yet decided to
place your trust in the Lord Jesus Christ
may never get another chance to do so
because you do not know when you will die.

This means that if you die without
trusting in Jesus Christ as your Lord and
Saviour you will be forever separated from
the love of God in a place called Hell.

The Holy Bible descibes Hell as a place of
eternal torment, suffering, pain and agony
for all those who have rejected Jesus Christ.

The good news is that you can avoid Hell by
allowing Jesus Christ to save you today.
Only then will you have true peace in your
life knowing that no matter what happens you
are on your way to Heaven.

Praise the Lord!
Servant of the Lord Jesus Christ
Ronald L. Grossi

The answer is obvious given that chimpanzee DNA is 98% virtually
identical to mankind's.

The much larger question is: Where did the first DNA come from?

I need a sanity check. I fellow told me he was getting a balun to get a better match between his receiver and antenna to get a better signal to noise ratio. I told him he was wasting his time and money because a better match increases transfer of both signal and noise. But since he already can hear the signal he doesn't need any more. Now if he was to get a more directional antenna he would get a reduction in noise from the undesired direction.

Your sanity's fine Hank. But why hurt the Balun manufacturer's business for the sake of an argument to no good purpose? Just tell this fellow that Radio Works (Portsmouth Va) will be happy to ship him a well made 4:1 Balun on the day of or day following his order. That helps keep a good company in business and it won't hurt your fellow's reception any.

Jack

Generally true if the external noise dominates the internally
generated receiver noise. This is the usual case in the hf region.
At vhf it is normally not so. Improvements in antenna gain
(directivity) and matching and reduction of transmission line loss all
can improve vhf SNR.

A balun *might* improve SNR at hf if the "feedline antenna" is more
susceptible to locally generated noise than the "real antenna" is.

A balun which reduces pickup ftom a nondirectional transmission line may
reduce noise too.

Best regards, Richard Harrison, KB5WZI

I would like to show you the one and only true path to heaven.

You are invited to attend service at "the Seventh Day Bhuddest Mosque" Mass
is at 11AM each Tuesday.

Those failing to attend are doomed to hell, this is your only warning!

I ran a test at my QTH with my horizontal dipole fed with
vertical ladder-line. I removed the balun-choke at the coax
to ladder-line junction. The noise level went up by almost
one S-unit. I suspect the culprit is localized vertically
polarized power line noise that has thwarted my every
attempt to use a vertical on 40m at my QTH.

That's apparently the case at my QTH, Wes. The localized
vertically polarized power line noise was about two S-units
on my 40m vertical attempt which rendered it useless for
weak signal DX purposes.

Hey, this is obviously a mass posting to God knows (irony intended) how many message boards; this guy is never coming back to check out our responses.

Interesting though, how empirical knowledge is achieved via willful belief, aka 'blind faith.' These people want to run our country based on this kind of thinking; they 'believed' there were WMDs in Iraq & they believe they'll 'save' social security via financial scamming. As the president said not too long ago, God has given the United States of America a special mission to lead the world -- and you don't f*** with God, remember that.

797. noise reduces when shield connection broken

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-15 15:45:26 UTC
From: Ralph Mowery <rmowery28146@earthlink.net>
Message-ID: <qkR7e.10122$44.5902@newsread1.news.atl.earthlink.net>
Source record: 79061

I have an off center fed antenna about 125 feet long and fed with a 4:1 balun . Then about 75 feet of rg-8x comes off at about a 45 deg angle to the house . It is then tuned with an MFJ tuner. Lately the noise jumped to about s9 or greater. I talk with some friends about 100 miles away. They will have an s9 + signal but are difficult to copy because of the noise. I found out that if I unscrew the coax from the back of the rig and just have the cneter conductor in , the noise will drop to almost an s-1 or s-2 but the received signals on 80 meters seem to be almost the same, still over s-9. I do hook up the shield to transmitt. The tuning does not seem to be any differant now than it was several months ago when I did not have the noise.. Any ideas on why the noise would be less but the desired signals seem to be about the same.

There was no signal present when I tried it. I'll
perform it again with a signal present. I don't
know what it will show if the signal is S-6 and
the noise level goes from S-3 to S-4.

I had the same symptoms and it was a broken wire.
Difference is that my autotuner complained.

Source record: 79066

Hello Gene:

I once lived in little community over looking the San Fernando valley in So California. I was surrounded by mountains and hills. I wanted to pick up a FM Broadcast station several miles over the hills.

I installed a modest FM Broadcast Beam or directional Antenna on a small mast with a rotor. I turned the beam antenna to the direction of the transmitter, but heard only bleed over from other FM Stations. I was disappointed about not being able to receive the FM Station almost 60 miles away. I turned the beam antenna now to all directions and to my sup rise I could now here the FM Station with good audio quality!

I was pointed the beam antenna in the wrong direction, but hearing the FM Station just fine. The Signal was bouncing off one of the mountains and I was hearing a reflection off the mountain. I was impressed.

I listened to other FM Frequencies and heard all different kinds of stations coming in from long distances. While listing to just one frequency and then turning the beam antenna I could get different stations coming in and other disappearing as the beam antennas was moving.

Using a beam antenna and rotor may save you a bunch of time and hassle. Even if you just find one direction that it works in for your application.

Jay in the Mojave

I could be mistaken, however, I think the radiation patten (and receive patten) would, at least, be slightly affected by a mis-match... whether this would justify going to extreme means of correction is debatable...

Here's a thought -- I'm using this mostly on 20 meters, and it seems to be performing well as a 3 x 1/2 wavelength doublet. I understand that with this setup, it fires off the ends rather than broadside. Since it fires off the ends would that mean a lower angle of radiation of the ends are higher? I'm thinking about getting the 35' end up a bit and perhaps end up with more like a non-inverted Vee arrangement.

Say I did download EZNEC. Dang that looks like a complicated program!

All DNA is virtually identical; fungi DNA, bacteria DNA, human DNA. It
is the genomes which are different.

> The much larger question is: Where did the first DNA come from?

Interstellar urea? :-)

Yes, but some is more identical than others. If I remember
correctly, 50% of banana DNA genes are virtually identical
to ours but it's 98% for chimps. (I never told you this but
I always thought you looked like a monkey's uncle. :-)

The "DNA Argument" is one which perplexes me.

DNA is but a building block, and one of a remarkable design; indeed, if it were software meant for execution on a hardware platform (processor) it would take countless programmers countless man-years to design and construct! (even reverse-engineering it is quite an undertaking!)

If DNA is related to our common "building blocks", it could be easily argued that 100% of the same "DNA" exists in a computer-which exists in an automobile, microwave or a transistor radio.

It all just becomes an argument that the creator(s) used the same "building blocks" in his/hers/its' creations.

Regards,

John

Please define "mismatch". An unbalanced 50 ohms to
balanced 50 ohms could conceivably be defined as a
"mismatch".

The above was too abbreviated to be useful, let me go further:

Of any species of prehistoric ape you can name, we have tons of bones, however, at the juncture where a wild transgression occurs, we have few (I think it is actually NONE!)

This is only proof of how closely our own design efforts manifest themselves as a direct examples of what we are viewing!

You do NOT see the steam engine slowly convert (evolve) itself into the internal combustion engine (and clear examples of all hybrids in between), you do NOT see the internal combustion engine "evolve" into the jet (turbine) engine-you do NOT see a flashlight "evolve" into a laser, you do NOT see a quartz crystal "evolve" into a PLL.

What you see are the same radical changes of where a THINKING mind has devised and instituted a DESIGN CHANGE!

When we first construt a lifeform from bits and pieces of DNA from existing creatures (or, even DNA we have crafted ourselves)--you will NOT see it "evolve." What you will see is intervention by a THINKING mind.

However, this is only one mans views..

Regards,

John

Yep, and the only question left is whether the "creator"
possesses a consciousness or not, i.e. was DNA just as
inevitable as a proton capturing an electron? I think
it was even though we don't fully understand the process.

Certainly true for engines. Certainly NOT true for living
creatures. Every small step in evolution is being filled
in except for where DNA came from in the first place. The
path from simple chemistry to amoebas is much more remarkable
than the path from amoebas to human beings. Given amoebas and
the right environment, human beings are inevitable. Given
chemistry, are amoebas inevitable? The answer is, yes, given
the right environment.

No. It only gets more complex, after (in the future) we are to
intelligently "resolve" these questions...
... then, there is the matter of the soul...

You now ask me to believe in something which there is NO example of (a single cell, reproducing, and the next instance existing as a multi-celled lifeform?) (and how about a virus becomming a single cell lifeform?)

If I can even see an example of something similar to what one is asking me to believe--I am much more likely to be able to foster a belief!

Feelings are good. How do you feel about paying taxes; and what effect
does that have on the amount you owe?

You know....
Funny you mentioned that, when I took accounting and learned it was a system
of debits and credits, a system employed by the Romans thousands of years
ago--before they knew about negative and positive numbers--before the
general population had a good/working knowledge of mathematics...
I smiled.... I think my accountant, surely, holds a stiff upper lip!

Isn't the Internet great? Any lunatic (not you Fred...I think :-))
with a computer and a phone line can be a preacher.

Too bad they all miss the real point of being a fire and brimstone
salesman and that's the ability to pass the collection plate.

Which reminds of an old Flip Wilson bit.

Reverend Leroy stands in front of his congregation in the Church of
What's Happenin' Now and says, "A Church is just like a child. In the
beginning it must learn to crawl."

Congreation: "Yeah Rev! Let it crawl! Let it Crawl!"

Rev. Leroy: "And after it learns to crawl, it can get up and learn to
walk."

Congreation: "Yeah Rev! Let it walk! Let it walk!"

Rev. Leroy getting into better form: "And after it learns to walk, it
can learn to run."

Congregation, now worked into a frenzy: "YEAH REV! Let it run! Let it
run!

Rev. Leroy shouts: "And for it to RUN...it's got to have MONEY!"

Congreation: "Let it crawl, Rev, let it crawl."

I think it would be possible to alter the "beam width" of the omni-antenna (mobile) and so make it "better."
If you take the time to learn EZNEC or MMANA you can view this for yourself in the plot of the radiation pattern....

Regards,
John

Many thanks to you all for your replies. I built a coax vertical antenna (two elements 1/4 wavelenght) using scrap water copper pipes. Only mediocre results are abtained with the antenna alone, but with an in-line amplifier..... thumbs up! A strong and useful signal.

Gene

Thanks John but that's not what I meant. For the record,
I'm trying to understand some manufacturer's claims that
the antenna they sell, while smaller than a 1/4 wave whip
on 10m, puts out a better signal.

Here are the rules:

1) The antenna is at least 25% shorter than a 1/4 w whip
2) The antenna is made with ordinary materials - no friggin gold.
3) The antenna is omni-directional & vertically polarised
4) The feedline is Flexi 4XL, aka CQ-102
5) The antenna is mounted dead center on the roof of a van.
6) The antenna's mount is non magnetic - I.E. There is a good
DC/RF ground at both the base of the antenna & the radio.

The way I see it is there is no way to make an antenna that
meets all those rules and STILL has more than 2.14dbi gain
due to resistave losses.

Am I right?

What was the "THINKING mind" that created God? The problem with the
if-you-find-a-watch-there-must-be-a-watchmaker argument is that it
leads to an endless succession of makers: the watchmaker, the watchmaker
maker, the watchmaker's maker's maker etc. which still doesn't answer
the question of what happened, where, and how, in the beginning, or even
if there was a beginning.
73,
Tom Donaly, KA6RUH

The question is: Given there are missing holes, do you want
a shaman or scientists to fill in the missing holes? I'm
willing to wait for the scientists.

You have got to be kidding. Your brain contains sequences of
bacterial DNA integrated into your human DNA long before humans
ever existed. How the heck do you think it got there?

Evolution is a scientific theory, not part of a belief system. If some
scientist were to come up with a theory that explained the biological facts
better he would get a Nobel and a job at a prestigious university.
In a religious society, he would be burned at the stake.

I do NOT claim to have the answer, only questions.
But, I do claim the "Mud Puddle Theory" is the easiest to dismiss--why it
has gained such popularity in the realm of human myths is simply beyond me!

Most kidding aside... I just don't know Cecil... the best I have to begin my quest with is the book of Genesis...

This book comes from a time before written history, the stories handed down generation to generation--by word of mouth, until we invented and developed writing, or re-developed it--no one knows its' true date of "creation", and it is error ridden because humans are fallible--I only believe someone seen the events which are described there--or thought they did... or ... the stories contain some cryptic bits and pieces of what were once complete memories... or ... it has survived through a time when we "lost" civilization and had to rebuild from the jungles, and this is all which remains... One clause there make me ponder in depth, as I remember it, "...and in that time there were giants."

I also have enigmas which stand as riddles explained by myth and misinterpretation--such as the pyramids and sphinx... there is also ancient Indian texts, from India, written on palm leaves and dutifully duplicated for uncounted millennia, as the palm leaves they were written on decayed and fell apart--which describe flying crafts, "lasers" and air battles--even what appears to be an atomic war...

The fact that these exist strike me as more bizarre than if the Romans were found to have written Buck Rogers comics!

If you press me further, I only have more questions...

Take a look at this fellow's website, he claims we were once "slaves" of the aliens, and they mined this planet... obliviously, he proposes some of us got left here--somehow--someway...

http://www.sitchin.com/

Do I believe this? No. Is it possible? -- "Well, it is as possible as any other damn idea I have heard some fool propose!" <grin>

Regards,

John

Hi Chuck what you discribe is about what I now have here also.. It
works ok.. not a beam but seems to work well on 80 , 40, 20 12 meters
..
The eznec plots look pretty good I have done some eznec plots if you
haven't done them yourself would be willing to send them to you .

The same is true for the American Indian religions.
Why adopt a European religion or Asian religion when
you could follow an American religion? :-)

A perfectly "omni" azimuth pattern is unlikely from a v-pol whip of any length when mounted on the roof of a van, however ~ 2.15dBi lobes could exist in some directions. The electrical environment around the van will shape the pattern further.

This could be modeled in NEC to give some insight into the situation.

RF

Yes. It is like trying keys in doors, hoping to find one which fits--only,
with some--there is no way to tell...
One thing ALL old societies have, either, a written record of, or a verbal
record of, is a great flood.
There is also a vast coating of mud in the geologic record--worldwide--I
would guess it is one important clue.
We are men with amnesia, no correct memory of our past, why we are here, or
what we were doing before we woke up...
Fools would say, "Looking for the answers is too hard--let's go party!"
I just smile and go about my business... looking... I used to run into many
others who were looking... has been some time now--maybe they gave up...

Regards,
John

One more thing...
Although the past seems hopelessly lost, I can "see" what seems clear to be our future...
We have been left perfect tools here. There is Mars. There are frozen moons at Jupiter. We could introduce vast greenhouses on Mars and begin to create an atmosphere. Hopefully there is abundant water there trapped in the rocks and elemental compounds which compose that planet--plants and the right conditions can release it--if it is there. Perhaps we could push a watery moon near it, and have Mars "suck" the water to it.
We could "push" a frozen moon of Jupiter into orbit of Mars, at a proper distance--and when we understand fusion--ignite it. Then, gently "push" this spaceship (the planet and light source) on a journey which can last indefinently--or perhaps, we can just look for others who have done this first (those DAMN aliens again!)... but then, we could just do nothing...
Like the X-Files, "The answers are out there..."
But, admittedly, this is far-far in our future--if we survive that long... I don't think I will be there to see it... frequently I fear humanity won't...
But then, if God shows up first--this is all a moot point...

Regards,
John

How does a mismatch affect the radiation pattern?
tnx .....

It doesn't. I don't consider unbalanced, the same as mismatched,
to answer Cecils question. Feedline radiation can effect the
pattern due to a lack of balun, etc, but thats not the same thing as an
impedance mismatch. Also...Antenna "loading" is not the same as
antenna "matching". Many short verticals need both...

Maybe I have a misunderstanding. I see a "mismatch" as being caused by only two factors, either an uncompensated reactance--or, as Cecil mentioned, feeding a bal/unbal antenna with the wrong feedline.
Indeed, any feedline can simply be analyzed as a series of lumped reactances--inductive and capactitive.
How should I be viewing this?

Errr, let me be a bit more specific...

The "beam width" of a quarter-wave has a very wide "acceptance ratio" and grabs much more reflection from the ionosphere--a half-wave has a much narrower beam width--it is a "quieter" antenna, but, grabs more of the signal I am after...

At least, it appears like that...

A five-eights-wave has even a lower beam width--these three antennas, because of length differences, exhibit differing reactances, when these reactances are cancelled (such as using an L-Match) they become "matched"--right?

Of course, this ignores conductor resistance, and takes for granted the antenna is being fed at the proper point...

A 1/2-wave VHF/UHF vertical has more gain at lower elevation angles than a 1/4-wave, but that may not usefully improve the SNR of the system. Most of the noise power in these antennas doesn't arrive from higher angles anyway, because those freqs don't reflect well from the ionosphere.

Source record: 78973

Does anyone have a user manual for an Outbacker Joey? If you could scan it or provide a few details, I'd appreciate it.

Also, can anyone tell me the difference between the WL-32 and WL-80? I've got one of each. Both models are marked "Joey," and both have the same band taps, and claim to be tuned to US bands. They are obviously differently constructed, though; one is slightly longer and has band taps at slightly different locations.

Finally.. if anyone is interested in one of these antennas, I only need one.

859. Re: antenna matching ??

Source record: 78974

No. Feeder radiation has *nothing* to do with impedance
matching. Zero. Nada...Zilch. Ever!...You can have a perfect
1:1 match, and still have feedline radiation. Or you can have
a horrible impedance mismatch, and have very little feeder
radiation. Feeder unbalance, lack of baluns, chokes, etc, etc,
should never be confused with impedance matching. I don't
think the term "mismatch" should be applied to a lack of balance,
etc...If you tell me you have a mismatch, I'll always assume you
mean impedance. Anyway, no matter my views...
Impedance mismatch will never change the pattern of the antenna.
For practical purposes, it's the same as raising or lowering power
to the antenna. If you run 50 more watts to an antenna, it's pattern
does not change. Ditto, if you run 50 less...MK

The reason some people don't know for sure if they are going to Heaven when they die is because they just don't know.

The good news is that you can know for sure that you are going to Heaven which is described in the Holy Bible as a beautiful place with no death, sorrow, sickness or pain.

God tells us in the Holy Bible how simple it is to be saved so that we can live forever with Him in Heaven.

"For if you confess with your mouth Jesus is Lord and believe in your heart that God raised Him from the dead, you WILL BE SAVED." (Romans 10:9)

Over 2000 years ago God came from Heaven to earth in the person of Jesus Christ to shed His blood and die on a cross to pay our sin debt in full.

Jesus Christ was born in Israel supernaturally to a virgin Jewish woman named Mary and lived a sinless life for thirty-three years.

At the age of thirty-three Jesus was scourged and had a crown of thorns pressed onto His head then Jesus was crucified.

Three days after Jesus died on a cross and was placed in a grave Jesus rose from the dead as Jesus said would happen before Jesus died.

If someone tells you that they are going to die and in three days come back to life

again and it happens then this person must be the real deal.

Jesus Christ is the only person that ever lived a perfect sinless life.

This is why Jesus is able to cover our sins(misdeeds) with His own blood because Jesus is sinless.

The Holy Bible says, "In Him(Jesus) we have redemption through His blood, the forgiveness of sins..." (Ephesians 1:7)

If you would like God to forgive you of your past, present and future sins just ask Jesus Christ to be your Lord and Saviour.

It doesn't matter how old you are or how many bad things that you have done in your life including lying and stealing all the way up to murder.

Just pray the prayer below with your mouth and mean it from your heart and God will hear you and save you.

Dear Jesus Christ, I want to be saved so that I can have a home in Heaven with You when I die. I agree with You that I am a sinner. I believe that You love me and want to save me. I believe that You bled and died on the cross to pay the penalty for my sins and that You rose from the dead. Please forgive my sins and come into my heart and be my Lord and Saviour. Thanks Lord Jesus Christ for forgiving me and saving me through Your merciful grace. Amen.

Welcome to the family of God if you just allowed God to save you. Now you are a real Christian and you can know for sure that you will live in Heaven forever when this life comes to an end.

As a child of God we are to avoid sin(wrongdoing), but if you do sin the Holy Bible says, "My dear children, I write this to you so that you will not sin. But if anybody does sin, we have one who speaks to the Father in our defense Jesus

Christ, the Righteous One."

Those of you that have not yet decided to
place your trust in the Lord Jesus Christ
may never get another chance to do so
because you do not know when you will die.

This means that if you die without
trusting in Jesus Christ as your Lord and
Saviour you will be forever separated from
the love of God in a place called Hell.

The Holy Bible descibes Hell as a place of
eternal torment, suffering, pain and agony
for all those who have rejected Jesus Christ.

The good news is that you can avoid Hell by
allowing Jesus Christ to save you today.
Only then will you have true peace in your
life knowing that no matter what happens you
are on your way to Heaven.

Praise the Lord!
Servant of the Lord Jesus Christ
Ronald L. Grossi

*Show this to your family and friends so
they can know that they have a choice
where they will spend eternity. Thanks!

The Death of John Paul II

John Paul II gained the whole world but
forfeited his soul. Year after year he
was the most loved and admired man in
the world. The idolatrous veneration
and adoration of this man was
unprecedented. His devotees, who are now
singing his praises, are probably
ignorant of the strong rebuke of Jesus
who said, "Woe to you when all men speak
well of you" (Luke 6:26). Had the pope
been devoted to Jesus Christ and His
Gospel of grace, he would have been
hated and persecuted by the world.
No one can judge John Paul's heart but
we are all called to judge the fruit of
our spiritual leaders. Clearly this man
was blinded by the prince of this world
and never saw the light of the gospel or
the glory of Christ. I mourn the death
of this man, not for the reason the
world mourns, but because he rejected
Jesus as God's only provision for his
sins. I also have a solemn compassion
for those who blindly followed this pope
and his man-centered religion. My heart
is painfully burdened to see so many
"professing" Christians unable to
discern truth from error and genuine
Christianity from its counterfeit.

huh? If you have an impedance mismatch, you are NOT feeding the antenna at the proper point, or with the proper ohm line, or without a proper matching circuit! Either one of these will exhibit some type of reactance!
OR! OMG! My "knowledge"/thinking is in error!
????

Ken, KG0WX wrote:
'Is it possible to make a mobile 10m antenna that is physically shorter than a 1/4 wave whip yet will perform better than a 1/4 wave whip?"

In general, the full-sized 1/4-wave whip is a very good compromise mobile antenna because it can be self-resonant, and it is almost omnidirectional in azimuth. Physically, slightly shorter than a CB antenna, it is readily available by trimming a CB antenna to resonance, literally, or by using a low-loss variable capacitor in series.

It is possible to use an antenna less than 1/4wavelengrh against ground as an efficient radiator but it requires care to minimize loss. Shortening the radiator reduces its vertical directivity. If gain is the performance measure, vertical directivity lost by shortening must be replaced, perhaps by horizontal directivity. Gain from horizontal directivity needs to cover not only lost vertical directivity, but losses caused by loading too-short elements in the array. These elements may produce horizontal directivity where none exists with a sole avertical element.

In the September 1973 "QST" is "A Bite Size Beam". This article refers the reader to an earlier March 1973 QST article by Sevick, "The W2FMI Ground-Mounted Short Vertical".

Summary: Can you do it? Yes. Is it practical? Maybe.

Best regards, Richard Harrison, KB5WZI

Of course, long, long before the bible changed his name
to Noah, Sumerian clay tablets report that great flood
in the "Epic of Gilgamesh" which predates the writing
of Genesis by many, many years.

> There is also a vast coating of mud in the geologic record--worldwide--I
> would guess it is one important clue.

If every bit of ice on planet earth melted, it would not be
nearly enough to cover all the land masses. As you would say,
the Genesis planet-wide flood that allegedly covered all land
masses has enough holes to fly a 747 through. :-)

You seem to hold your religion to much, much lower standards
than the standards to which you hold math and science. Shouldn't
something invented by God be held to much higher standards than
something invented by man?

Note Webster's has a different definition of mismatch
than the IEEE Dictionary. That's why I asked for a
definition. For instance, going from a black coax to
an orange coax could be called a color "mismatch".

From: Roy Lewallen <w7el@eznec.com>
Message-ID: <1163gnobv39ks11@corp.supernews.com>
Source record: 78890

A two conductor transmission line, with Earth or other conductors providing a potential third conductor, has two defined impedances. One convenient and intuitive way of defining these two is as common-mode and differential-mode (or even and odd mode) impedances. Our measurement equipment invariably measures the differential (odd) mode impedance, so when we speak of impedance "matching" or "mismatch" we virtually always mean matching of differential mode impedance.

Differential mode currents don't contribute to radiation. Differential mode impedance match or mismatch has no effect at all on antenna pattern. It can have an indirect effect on antenna *system* performance due to potential losses in impedance matching components. But otherwise the quality of impedance match can be ignored when considering antenna performance.

Common mode current radiates, so a transmission line carrying common mode current (a twinlead line with imbalanced currents, or a coax line with current on the outside of the shield) is actually part of the antenna. Anything which alters the current flow or distribution of this current (for example, a current balun) will alter the overall radiation pattern. If a transmission line is perfectly balanced, the common mode current is zero, and the term "match" or "mismatch" can't be meaningfully applied to the common mode impedance.

They burned the first cable up. Just more voltage than it could handle.
Thats why it lasted 20 days.

PBS Stations are independent stations and usually Tape Delay programs,
the Date and Time of the program will be different for every station.

887. Question on bi-conical antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-17 03:41:05 UTC
From: Ed <Huckleberry_REMOVE_@bigvalley.net>
Message-ID: <Xns963AD27D7CACFspectrumhogstarbandn@207.106.93.175>
Source record: 78902

The May 2005 issue of QST had an interesting antenna article on page 33... basically discussing broadband dipoles. I am particularly interested in the biconical (fan) dipole discussed. It is basically two dipoles common at the feed point, with a slight divergence out to the ends. I believe they discussed a spread of 6 feet at the ends for an 80 meter version.

This antenna may be just what I was looking for to put up on 75M.
Do you antenna experts here on this list have any opionions on this? I prefer "resonant" antennas fed with coax as opposed to open wire feedline with tuners, but I would like to be able to operate over the entire 75M band with my IC746Pro.. Comments?

Aside from a few errors in the article, (ie: 4*2.8 does not equal 10.2) If your going to use open wire feed, make the antenna 135 feet. See Cecils site, Cover all bands and save a bunch of wire.

I have used a number of methods over the years to cover 75/80 with a single antenna. A 12" diameter cage works well at low heights. I used sections of 12 " sewer pipe cut 3/8" thick and 6 wires coming to a cone at the end.

Reg has a program that shows bandwidth vs. Cage diameter. My practical results achieved greater band width than predicted by the program. Then again It was at 30 feet.

Some things that do not work, "the bazooka", dual wires spread less than 15 feet, and any of the antennas that are terminated folded dipoles.

Here is another one. A virus is a more simple "living" (there is debate if it is alive or not) organism than a bacteria--suggesting that the bacteria "evolved" from the virus--however--a virus cannot reproduce with out the bacteria!!! A real chicken-and-the-egg puzzle!
Again, I claim this as evidence of a creator--indeed, I recognize and love his warped sense of humor... <grin>

Fred, I appreciate your comments on my questions. Could you elaborate on your statement (above) that "dual wires spread less than 15 feet" do not work? The QST article, Table 1, seems to indicate they do work, with a spread of only 6 feet, or even 3 feet, for 75M dipoles.

Cecil:

What is God?
I do notice, that here, some seem to view any reference to God (him/her/it/???) as a "dictorate" figure of myth--one which they know cannot possibly exist, which holds them to an impossible standard, which they fear; but, he might just be a guy I'd like to go have a beer with! ... a lonely old man which wanted pets... or an alien kid who needed an experiment for his science fair... who knows... "they" claim his existance is an "obivious deception/myth"--but quite obiviously, they cannot know this--they practice a "religion" of agnostic or atheist... they think this proves them an "intellectual", since for some unknown reason it is popular to think "intellectuals" are athiests/agnostics... all they prove me to me is that they DO NOT belong in a jury box--and they make claims which stand against things clearly in the shadow of doubt (granted the doubt is a two edged sword)...
I hold to the ten commandments more because it makes me a good neighbor than for my fear of God--much more! However, I would fail much more often if I did not, at least, suspect that these laws came from a "higher power"...
I try not to assume anything--and frequently fail with the most obivious appearing/looking objects--I fail--I try again--etc... hey, sue me... <grin>

Warmest regards,

==========

My program, DIPCAGE2, is concerned with the bandwidth of a cage dipole in isolation.

But the type and length, in wavelengths, of the feedline has a considerable effect on the bandwidth of the radiating SYSTEM as a whole. And a tuner, if used, also plays a part.

It is not surprising that practical measurements made from the shack randomly indicate somewhat different bandwidths. But neverthless the bandwidth of the antenna itself, as predicted by the program, plays the principal part.

In general, the bandwidth of an antenna does not increase in proportion to its efective diameter so much as is often fondly expected. But it is not a critical performance characteristic.

Reg, G4FGQ

Reg, I was not impuning your program. I used it as a guide and found that it followed my actual findings once I scaled the results for my particular location.

My point was that at the heights most of us "mere mortal" hams are able to achieve, one can cover 75 meters with a 12" diameter cage.

Maybe I misunderstood the point below, but it looked to me, from examining the empirical data presented in the article, that a spread of 6 feet did a decent job of broadening the swr curve of a 75/80 m dipole.

If 6' worked so well in the article, why are you saying "dual wires spread less than 15'" as something that "doesn't work" ? Are you discussing something else?

Ed, this comes from years of practical experience in trying to achieve a broad antenna.

With all due respect to the various "NEC" programs as well as Reg's program, they are great for comparing antennas. In the real world environment of most hams, results do not agree with the predicted on 75.

Why?, because few of us can get a 75 meter antenna any where near a half wave length high and in the clear. While one may be able to model the real antenna environment, I am not smart enough. I would suggest that you model your particular 75 meter antenna, and then measure actual results as a fun exercise.

Now to the original question, in spite of the data in QST, I have found spreads of less than 15 feet in a practical environment will not achieve your goal. YMMV.

We have got to the point in ham radio, we are measuring with a micrometer, marking with a crayola, and cutting with an axe. I doubt that anyone in the history of the world has calculated a 75 meter dipole, put it up, and made no adjustments unless they mis-measured.

Heck for years we have used 468/F to cut our antennas and that is incorrect as well! Don't rob yourself of the fun of trying something based on a program. Last night, for example, I had an enjoyable ragchew with a fellow in England, running my barefoot Icom 706 MKIIG on 75. My antenna is 40 feet up at it's highest point. Anecdotal evidence for sure, but the QSO was fun anyway!

Sorry to get so long winded... Good luck on your broad antenna experiments, the journey is the fun part.

They make a 12" PVC pipe. I got some scrap sections from the guy who put in sewer lines in my town.

The pipe is cut in such a way that you have rings 12" in diameter and 3/8" wide. Holes are drilled every 60 degrees. I use 5 rings on each end (10 total). The wires are tied together at the center and end insulators.

I normally tie a wire between a tree and the hitch on my pickup with the 5 rings pre strung. Then add the other 5 wires. Once the whole mess is put together slide the rings an equal distance apart. The ones at the ends should be 18 inches from each insulator. Use 6 inch pieces of wire to anchor the rings. Wrap a couple of inches around the wire, over the top of the ring and continue wrapping on the wire. 3 per ring works well. Being cheap and as this antenna uses a LOT of wire I make mine out of electric fence wire (1/4 mile for $7.00). Get some help holding the ends as you raise it. If not you will end up with the worlds biggest "slinky".

Ed, this comes from years of practical experience in trying to achieve a broad antenna.

With all due respect to the various "NEC" programs as well as Reg's program, they are great for comparing antennas. In the real world environment of most hams, results do not agree with the predicted on 75.

Why?, because few of us can get a 75 meter antenna any where near a half wave length high and in the clear. While one may be able to model the real antenna environment, I am not smart enough. I would suggest that you model your particular 75 meter antenna, and then measure actual results as a fun exercise.

Now to the original question, in spite of the data in QST, I have found spreads of less than 15 feet in a practical environment will not achieve your goal. YMMV.

We have got to the point in ham radio, we are measuring with a micrometer, marking with a crayola, and cutting with an axe. I doubt that anyone in the history of the world has calculated a 75 meter dipole, put it up, and made no adjustments unless they mis-measured.

Heck for years we have used 468/F to cut our antennas and that is incorrect as well! Don't rob yourself of the fun of trying something based on a program. Last night, for example, I had an enjoyable ragchew with a fellow in England, running my barefoot Icom 706 MKIIG on 75. My antenna is 40 feet up at it's highest point. Anecdotal evidence for sure, but the QSO was fun anyway!

Sorry to get so long winded... Good luck on your broad antenna experiments, the journey is the fun part.

73 Fred W4JLE

The Deep South 2 Meter SSB Net is growing by leaps and bounds every evening at 8:30pm CDT. We get together on 144.240 USB and have a great time. There is an open Swap Meet each evening after the net. Net control is AD5TH in EM52 near Union,Mississippi.

The Deep South Net is now a week old and already we have 18 ssb ops on the roster. We have regular check-ins from Mississippi,Alabama,Arkansas, and Tennessee. Our webpage is www.deepsouthnet.net and has received over 800 visitors since April 6,2005. Join us every night at 8:30pm CDT on 144.240 as we swing the beam your way! 73 / DX Charlie - AD5TH

Humans have always used their ignorance to justify the
existence of a supernatural. One possibility:
The evolutionary ancestor of a virus may have once been a
bacteria or some other extinct life form. The most common
life form on this planet was recognized as being alive only
a few short years ago.

Thanks. I wasn't able to find any answers there, though. I didn't know about the Jr+, but I don't think I have one if I can trust the markings. I'd really like to find some promised impedance graphs, and some guidance on what to do with the adjustable whip. I can always try emailing them, I suppose.

Message-ID: <1164uf05ta1ii07@corp.supernews.com>
Source record: 78975

Dear Jim (KC7JFV):

I am surprised that Richard Clark's useful comment was not augmented.

A projection that is most helpful to the visualization of antenna
patterns is the Sanson-Flamsteed projection. It is an equal area type of
projection sometimes called the sinusoidal projection. I first saw this
projection being used in the classic antenna pattern book published by the
ITU in the 1950s. Its usefulness is awesome.

The idea of this projection is simple. The (new) y-axis is equal to the
elevation angle (above horizontal) of the antenna's pattern. This is often
expressed as y = latitude.
The (new) x-axis is equal to the azimuth either side of a particular azimuth
(usually selected as the azimuth containing the peak antenna radiation)
times the cosine of the elevation angle. This is often expressed as:
x = longitude times Cos(latitude).

Keep in mind that the latitude/elevation angle must be expressed in
terms of a type of angle (degrees, radians, grads, etc.) that is compatible
with the available Cosine calculator.

The projection is not a device, but it is a means for visualization that
I have found over some 50 years to be ideal.

Due to time zone differences, that is probably the best approach. I have
not seen as much documentation on the Joey, compared to the earlier antennas
(I have an Outbacker)

912. Hustler 5BTV Radial Question...

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-17 16:21:24 UTC
From: "Michael Melland, W9WIS" <mmelland@centurytel.net>
Message-ID: <IfSdnQ8mA8SbEP_fRVn-sQ@centurytel.net>
Source record: 78977

I moved in December and was hoping to install a ground mounted Hustler 5BTV vertical at my new place. I had hoped to lay down a good set of radials under the vertical for better efficiency then the GAP Titan I had previously.

In reading various sources it seems I need radials that are length coupled to my lowest frequency of operation. Although I have 10 acres of land the clear spot I was going to mount the Hustler in gives me only about 25 feet in circumference for the radial bed. Fine for the higher bands but what about 40 (31 ft) and 75/80 (62 ft)? For 40 meters I could just bend the ends of the radials to fit and for 75/80 I know that I can zig-zag radials to fit but can I cross lay them over the extended 40 meter radials ? Would I be better off instead of cutting radials for the various bands to just lay all 25 foot long radials ? Or.... should I junk this plan and just put up a GAP with no radials ? I had hoped the Hustler might give better performance.

True. If you propose a workable theory, such as:
It took billions-of-billions-of-years for us to "evolve"...
Or, aliens found simple lifeforms in another universe and engineered some
lifeforms which they carried here...
Or, ?????.....
You would set my mind pondering in yet another direction...

Regards,
John

It is not inconceivable that some advanced civilization
decided to seed their galactic neighborhood with primitive
life forms from their planet using long-range autopiloted
vehicles. An abundance of simple life forms seem to have
appeared rather suddenly on this planet about three
billion years ago.

Did you really mean 25 feet in circumference? I am assuming you really mean radius. As long as the radials are equal to the height of the antenna you will be in pretty good shape.

I have found the same thing. I was able to dig up a few product reviews, but no technical information. I'm working on a web page about the Joey right now for posterity. I've got an SWR analyzer and a portable HF rig, so I'll take it out to a greater-than-one-wavelength field and make my measurements out there.

I did make one discovery today, though. "WL-32" is an Outbacker part number for the "Wander Lead," the banana wire that you re-patch to change bands. The WL-32/80 is apparently not the antenna; it's marked next to the bottom tap, to which one end of the WL is supposed to be attached. The other end goes in the tap marked with the desired band.

Because the lead is 32 inches long, I suspect that a WL-80 is just a metric version of a WL-32. I am also guessing that because the antennas are hand made and that specifications are always subject to change, the different lengths of the antennas are insignificant.

Hi Fred,

Yes.... sorry for not being more specific, radius. I can go out farther but then it's up in my yard where I mow pretty low. The 5BTV is ~24 feet tall.... I have heard this formula for radials before.... but, is it really meant actual "physical" height of the radiator and traps or is it really meant to be the theoretical electrical length (height) of the radiator ?

And... I got the antenna and mounting/radial system from DX Engineering.

Mike, W9WIS

The physical height is fine for a ground mounted vertical. With the DX engineering kit you can put down a bunch of radials.

I was always too poor for all those nifty things. I normally use the lid off of a 55 gallon drum.:>)

Dear Fred (W4JLE):
Oh my. I never thought of PVC 12" sewer pipe.

Thank you for that, and the other, details. I will be on the lookout
for such pipe and measure its thickness. Apparently, the pipe is strong
enough that the end supports do not buckle. I would have expected to need
supplemental braces on the end supports.

Presumably, the electric fence wire is solid aluminum. If so, you must
use a pair of substantial clamps at the feed point and some sort of Al to Cu
transition.

Thanks. 73 Mac N8TT

I never used clamps, simply put the 6 wires through the eye of an insulator and wrap it back on it's self.

The pvc is plenty strong enough, I think the last ones I made the pipe was almost 1/2" thick outside to inside.

I have used a number of different type wires, one made from enameled copper wire #18 was neat. You almost could not see the wires at certain times of day and had the illusion of the rings floating in the air. At another time of day the sun hit it just right and appeared to be a solid copper pipe hanging in the air. I have used both Au and galvanized wire and for all practical purposes they operated the same. The fence wire is #16.

For the connection I normally use brass contacts salvaged from an old electrical panel. They seem to work well and last a long time.Let me define my long time, I rarely have an antenna up more than 2 years as I am always trying something new.

I have been thinking about getting an Outbacker and using it with a 3 magnet mount for my van and SUV. What is your opinion/s of this setup. It appears that height will not be a problem with it hitting anything. Thanks for your opinions.

940. S/N ratio question - have I got this right?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-17 22:30:17 UTC
From: Ken Bessler <kg0wx@NOSPAMyahoo.com>
Message-ID: <ZrB8e.2850$mS1.499@okepread04>
Source record: 79005
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.equipment

Someone check my math, please? I'm using
a program called "Cool Edit Pro" which can
give me very accurate readings of tone levels
coming from my FT-857D into my soundcard.

I'm trying to develop my own way of evaluating
my new vertical's (Cushcraft R7000) performance
compared to my dipole. I'm starting by tuning
700 hz off of WWV's 10 mhz carrier and recording
the tone I get in USB mode with my AGC off. I
switched antennas during the recording and took
2 samples:

1st example Cushcraft R7000
Noise @ 2k = -39.27db
Signal @ .7k = -7.26db
S/N difference = 32.01db
S/n Ratio = 14.662

2nd example 40m ladderline fed dipole
Noise @ 2k = -30.11db
Signal @ .7k = -8.864db
S/N difference = 21.246db
S/n Ratio = 10.622

For some reason my program gives me the back-
ground and signal levels in negative DB. I used
this formula to come up with a S/N ratio:

S/N = 20 log10(-dbs/-dbn)

Can someone check my math? My guess is
that my R7000 is better at WWV for this test.

From page 20.20 of my Arrl 2000 Handbook: "...a large number of
shorter radials offers a better ground system than a few longer ones.
For example, 8 radials of 1/8 wavelength are preferred over 4 radials
of 1/4 wavelength. If the physical height of the vertical is 1/8
wavelength, the radial wires should be of the same length and
dispersed uniformly from the base."

OK - that sounds like a great setup
I have had best luck with running at least 3 or more of the specified length
in the Hustler manual.
Longer does not seem to improve.

Yes, the wander lead always goes at the bottom position, sometimes only
marked as WL (as my Outbacker does) - then you wrap the lead around the whip
to the desired "tap" for the band (e.g. 40 M) you are going to use - and
plug Wander lead plug into that tap.

I'm pretty happy with the Joey (which is not recommended for mobile use btw), but these suckers are expensive, and if you only operate one or two bands, you won't get your money's worth out of it. I'm going to have to force myself to branch out from 20 and 40.

That said, you get every band in one piece of equipment, with no loose parts to lose and no power requirement, and there's something to be said for that.

OK. Let us get clear on this point...
What other object, thing or being, in the whole universe--is an example that "nature" is a constructive force. A force which is naturally conductive to the formation of complexity, symmetry, intelligence and self-replicating creations.
Point out all the other things which are an example of this force at work--EXCEPT THE SOLE OBJECT IN QUESTION (life on Earth)--as if this IS a trait, a method, a law of nature, examples should be most abundant!
No. Life on Earth is the only such example...

Nature and time erode, decay, and randomize... all you will see nature create are spheres (largest volume contained in the smallest possible shape) and crystals (simple geometric shapes governed by the shape of the molecules of the material)....

Warmest regards,
John

CoolEdit always references with 0 as the maximum signal level; i.e.,
32768/-32767 are max for 16 bit recordings. This viewing mode is
selected with View -> Vertical Scale Format -> Sample Values. You may
also select Decibels, Normalized Values, etc.

I have CoolEdit 2000. Is yours a newer one since the company was bought
out?

When you did the level check, how was that done? Did you select Analyze -> Statistics and run it against a marked area in the recording for an average? If so, how long was the average? Did you run a filter first to isolate the signal from the "noise"? Or did you run the FFT function?

Signal to noise ratio is the difference between the signal and the noise.
i.e. In your
first example: -8.864-(-30.11) = 21.264 dB.

Not sure what you mean by quoting levels in "dB", since it must be
referenced to a
specific value. Assume it is "dBm".

A sky wave signal should be averaged of a long period to estimate the actual
signal level.
Also the RF gain must be backed off so the receiver is not saturating from
the input signal.

Your "20log10" is the expression used when calculating the dB ratio between
two voltages.
Assume you mean "Log to the base 10".

Hope this helps.

73,

Frank

Sorry, I should have said 0dB, and then that samples are referenced to
integer values which can be viwed, etc.

This damned sinusitus. I can begin to see why people who are really
sick, as opposed to what I have, get to the point where they want to
give up trying to continue to live.

I have 2.1 and I'm still learning. I didn't do a level check
- I was only wanting to compare 2 antennas, not establish
an actuall DBv reference.

958. Re: Hustler 5BTV Radial Question...

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-18 02:36:29 UTC
From: Hal Rosser <hmrosser@bellsouth.net>
Message-ID: <EYE8e.77783$f%4.73113@bignews1.bellsouth.net>
Source record: 79023

You can bury the radials using a chain saw, or edger, etc. Just slip wire into slots in the ground.
And if you turn on the lawn sprinklers for a few minutes, you may see some improvement.

959. Re: Question on bi-conical antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-18 03:09:28 UTC
From: Hal Rosser <hmrosser@bellsouth.net>
Message-ID: <zrF8e.77797$f%4.76409@bignews1.bellsouth.net>
Source record: 79024

the search for the broad band antenna continues.
It appears putting more wire in the air is the preferred solution,
but more wire means more weight
more weight make the antenna droop - and can break a tree limb.
a dipole fed with ladder line is lightweight.
it doesn't droop
it doesn't break limbs
it works
I like Cecil's antenna at his web site. A few 4pdt ice-cube relays @ 7.50
each and the sockets @ 2.50 each can switch different lengths of ladder line
in and out. Put the line and relays in the attic.
I think you could also make use of an old TV tuner switch (The old clunker
channel changers)
I considered using a PLC to switch the relays.

You are arguing that because doctors couldn't see germs before
the 19th century, germs didn't exist before the 19th century.
Not only is there, no doubt, an abundance of life in the universe,
but I'm willing to bet there is life on other bodies within our
own solar system. What will you do when we discover life on Mars
and/or Europa?

We now understand the mathematics behind Mother Nature's ability to bring order out of chaotic systems. There's no mystery to it any more. When I first tried to generate the Mandelbrot set, I made a slight programming error in the calculation such that X and Y were not independent. The result was ears, arms, legs, and sex organs on the Mandelbrot character. Varying the degree of interaction between X and Y resulted in either masculine or feminine characteristics. Want me to send you a copy?

Those slight DNA programming "errors"
in nature are called mutations. The great majority are failures but once in awhile along comes a success that generates a new species. The mutation that resulted in Homo Sapiens has been backtracked to a single female in Africa who lived roughly a quarter of a million years ago. That particular mutation required an X chromosome. There was an Eve but no Adam. :-)

Again, thanks for the comments. For clarification, though, could you describe what you mean by the 15 feet spread for a 75M antenna? The QST author is describing a biconical antenna with two dipoles tied common at the feedpoint, but spreading out a couple degrees to the ends.... his figures indicating 6 feet at the ends working, but 15 feet the spread if using the recommended 2.8 degree angle from the apex.

Is this what you mean, or are you describing two dipoles separated their full length by 15 feet?

Ed

I got my relays for $2.50 at surplus stores in Silicon Valley.
I finally settled on knife switches mounted on Plexiglas in my
hamshack window.

No. You attempt to change my argument...

Let me provide an exact definition of my argument, if my past posts disclaim this, point it out...

1) I do not know mankind's origin and my investigations only bring me more questions--I attempt to hold an open mind--but find I STRONGLY suspect a high power, a thinking mind, has been at work.

2) Mankind's origin is THE most important event since the creation of the universe and I am perplexed by anyone who is not intensely interested in an answer.

3) No one knows the truth and God is equally as plausible as a mud puddle or an alien--however, there is one other possibility which is remotely possible; An elite group (perhaps decedents of the money lenders from the original temples or the Egyptian priests--perhaps existing like royal blood line, and which knows no countries borders or holds an allegiance to any specific people(s)) could exist which has the knowledge and does indeed know the truth, but keeps it hidden for purposes of their own (greed, wealth, power, control, etc.) But, I only consider this REMOTELY possible, and a fantasy I allow myself (I like science fiction and mysteries too)...

4) It is even possible aliens are here and their stealth technology is so good we are ignorant to their presence--and ONLY remotely possible they have set up a "duck blind" and electromagnetic shield on this portion of the universe which deafens our most powerful radio-telescopes, and study us as we would some species of lower animal--intentionally hiding their presence so as not to influence their scientific studies.

5) Any possible belief, or any possible theory which can be mentioned, is nothing more than a pseudo-religion and taken as leap of faith--proof of any escapes us.

6) A myth has formed where agnostics/atheists are viewed as "more intellectually inclined"--why is a complete mystery to me.

7) We ARE alone--if there were others, in the trillions of "planet years" (if not trillions-of-trillions of planet years) which has transpired since the creation of the universe, they would have left traces and clues of their existence.

I tend to almost completely laugh off elements of 3 and 4 above, but mention them for completeness...

I interact in chat, discussion, reading, research, argument and debate with most anyone because I am still looking... my investigation is nothing more than a mental diversion--a hobby... I expect a kid next door to be about as likely to provide clues as I do the most respected professor of any notable university...

As for life in our solar system, our planet could have been seeded from a fatal event which happened to mars--and ancient asteroid which struck earth could have sent matter out and seeded Mars-none of this would not surprise me, indeed, it may have even seeded other solar systems...

"God" (you say nature) does indeed know how to use the square root of negative one, and treats imaginary numbers as if they are real!!!!

Regards,

John

Also, you mention programming (I am a coder/white hacker yanno!) DNA does indeed look like a computer code to me (shame it won't run on an IBM platform, doesn't look like Motorola either--and who needs a bad apple? (well, there was that girl, once, what was her name? EVE?), and the most interesting part is what biologists call "junk DNA" (the worm?--malicious code). If I was God (wishfull thinking, huh?) I would have hidden my signature here! <grin> So the boss wouldn't find it, but those thinking minds, I'd like to meet, would discover it (maybe my post office box is there! phone number? "Gods signature" would most likely give his number and say, "ET! Phone home!) <<== for you Richard :)

Oh, I'd be looking for them alright--"he" just might be... then again, I think I read that part in a SF novel! Or, a movie?

Warmest regards,
John

Back in the 80's I had a buddy who was an IBM fellow.
His office at Watson was next to Mandelbrot's.
There was one picture on Benoit's door: Gauss.

Everyone should have realized by now that there is no
information about antennas in this thread.

The last verticle I had up was a 4BTV. I mounted it on top of a chain link fence. I bonded the top rail to the mount pole and bonded the link fence part as well. The top rail was at least 40 feet either side of where the verticle was mounted. I got out like GANG BUSTERS! Usually people who complain about verticles not radiating well are the ones who don't work them against a good ground reference. 17 years as a broadcast engineer put me onto good grounds....

>Am I right?

I was a friend of Jim Taylor and Jim Taylor Jr. of Taylor Radio back in the good-ole CB days. Sitting at lunch one day we were discussing the old Big-Stick and Grand Slammer antennas (I think those are the names of the 5/8 wave base verticals most popular in that day). They told me that the market ting departments of the two companies made more antenna gain progress than their engineering departments did.

I was slow to understand the statement at that time, so they explained that every time one came out with an ad, the competitor had to match or beat it. While the comparisons started with a 1/4 wave vertical, Jim said that if it continued, antenna manufacturers would have to start comparing gain to their antennas against loaded coat-hangers.

In the truck stops, there are several antennas that are shortened 5/8 antennas. I think that is the case with Fire-stick. I can't tell you if it has a gain or loss over a 1/4 wave whip.

Just a side-note tho... I have a 706 MKII in the car. I had a 6 meter whip on a mag-mount connected to the HF side where I was listening to a local beacon. I removed the 6 meter whip and replaced it with a White GMS/Volvo CB whip about an inch shorter (the cb antenna is just under 4 feet long.) The signal of the 6 meter beacon came up from 1/2 to full scale. I swapped back and forth and tested the SWR to make sure. The CB antenna was maximum SWR but sounded considerably better. I have several of these antennas so I am planning to try to trim one for 6 meters and use it instead of the whip I am using now. I don't have enough data to determine what causes the improvement, but I believe I have ruled out propagation.

Ed, spread 15 feet at the ends.Nothing critical once your beyond the 15
feet.

I have varied the lengths of the legs, where one is longer than the other.
For example think of two dipoles one cut for 3.6 and the other cut for 3.8.
I have also played with 4 wires spread 2 vertical and 2 horizontal.

The biconal has been around for ever and was widely used in the old TV
antennas to broadband the response.

If there is any interest, I could dig out my old notebooks and post the SWR
tables of a bunch of designs.

You should have checked several becons in diffearant directions. A few
years back a friend and I had several 2 meter antennas that would fit the
same mount. While checking out several repeaters in differant directions we
found one antenna would be beter in one direction and another in a differant
direction . It may have been due to the differance in the lobes of the
antennas and the height of the repeaters.

Ed wrote:
"I prefer "resonant" antennas fed with coax as opposed to open wire feedline with tuners,---"

Bamdwidth of a resonant antenna depends on its antenna Q. A high-Q antenna can cover a wide band by retuning for the frequency to be used.

Biconical antennas are used for their feedpoint impedance of about 72 ohms and for their low-Q (wide bandwidth).

A high-Q loop antenna can be efficient and smaqll but must be tuned for the frequency of use. An interesting example appears in the July 1968 QST. It`s the cover story.

The loop is a rectangle 8 feet long and 4 feet wide made of copper-plated aluminum rain downspout. It is tuned and loaded with dual-section 500-pf variable capacitors such as pmight be used in a TRF set. With additional switched-in fixed capacitors, it matches 50 ohms from 2.8 MHz to 7.3 MHz, and from 14 to 22 MHz. It also works to 30MHz with an SWR under 3:1.

This mobile antenna was mounted on a car roof. Some YL`s may not appreciate its beauty.

Best regards, Richard Harrison, KB5WZI

It is true that the other half of the vertical antenna is the ground effect. This cannot be emphasized enough. I have 72 radials (about 1300ft of wire) under my ground mounted 5-BTV and I too am very pleased with the results. I also used the DX Engineering stainless steel radial plate and tilt over mount. Many many photos of this installation at my web site listed below. The spring grass growth has covered the radials (previously covered with soil too) now and I am mowing right across them with no trouble.

My 5-BTV assembled easily and tuned right up (swr plots on web site too). It is by no means an eyesore but instead is sleek and really quite attractive as ours in is the front portion of our side yard. So far it has held up to winds with no guys.

Check it out at the site listed below....

To gain an idea of the performance of an Inverted-V, as the included
angle varies from 180 to 0 degrees, download program INV_VEE from
website below. Takes only a few seconds. Run immediately.

Source record: 78850

No "signal cancellation" occurs at any angle. Except for conductor loss, every watt of power you feed into it is radiated, regardless of the angle. What does happen at narrow angles is that the radiation resistance drops, which can increase loss, although it typically has to drop quite a bit before the increase is significant. It also narrows the antenna's bandwidth, so you'd have to retune after a smaller frequency change.

986. Two Element Beams

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-18 20:40:43 UTC
From: Cecil Moore <w5dxp@hotmail.com>
Message-ID: <42641c15$1_1@127.0.0.1>
Source record: 78851
Body handling: Binary attachment payload not displayed: phsdips.EZ, phsdipst.EZ

Years ago I experimented with two-element beams where both elements were driven. Roy, W7EL, has some BASIC programs on his web page that allows the calculation of phasing harnesses for such antennas. The disadvantage is that one must know the mutual coupling impedance between the two elements.

Given that EZNEC will output the feedpoint impedances for both elements, for a common class of two-element beams, the mutual coupling impedance can be calculated from the EZNEC data. Assuming the two-element beam consists of two identical center-fed elements and assuming that the feedpoint current magnitudes are equal, one can design the beam to meet certain specifications, obtain the feedpoint impedances from EZNEC, and calculate the mutual coupling to be entered into Roy's BASIC phasing software.

For instance, attached is phsdips.ez which is a wire two-element phased beam for 20m with a gain of 12.32 dBi. The model uses two equal current sources fed 135 degrees out of phase. The feedpoint impedance, R1 + jX1, of element#1 is 17 - j56.08 ohms. The feedpoint impedance, R2 + jX2, of element#2 is 31.63 + j8.1 ohms. PA is the phase angle between the current in element#1 and the current in element#2 and is -135 deg because, by convention, element#2 current lags element#1 current. (PA) is the phase angle.

Rm, the mutual coupling resistance = (X1-X2)/2*sin(PA)

Xm, the mutual coupling reactance = (R2-R1)/2*sin(PA)

Rm + jXm = 45.39 - j10.35

Rs + jXs is obtained from EZNEC using only one element and one source. Since the two elements are identical, Rs + jXs will be the same for both elements. For this antenna, Rs + jXs = 56.58 - j30.42 ohms.

phsdipst.ez is also attached and shows what happens when the coaxial phasing harness is attached. Gain is 12.3 dBi. These coaxial phasing lengths were obtained from Roy's Lewell1.bas program available as simpfeed.zip on www.eznec.com.

One advantage of a wire beam like this is that the direction of maximum gain can be reversed by changing the feedpoint

position on the coaxial phasing harness. Good E-W or N-S
beam performance is obtained with one fixed wire beam on the
lower bands.

987. Re: Two Element Beams

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-18 21:05:02 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <11688877d34d749@corp.supernews.com>
Source record: 78852

You must have missed the announcement I posted not long ago. The article about transmission line phasing systems ("The Simplest Phased Array Feed System - That Works") is now available at http://eznec.com/Amateur/Articles/. And there's also a new Windows Simpfeed program which takes EZNEC (or other modeling program) reported feedpoint impedances as its input (no mutual Z calculation necessary) and calculates the feedline lengths necessary for proper phasing. Click the Simpfeed link at that same URL to get it. It's considerably more versatile than the older DOS programs. A short manual, including a detailed example (using both the EZNEC demo and the standard EZNEC program type), can be viewed by clicking the Help button in the program window.

EZNEC example files CardTL.EZ and 4SqTL.EZ illustrate the results of using this feed method. The new program does all calculations in double precision, so you'll find the values it generates are slightly different than the values in the example files -- they're actually better.

988. HF ANTENNA TO SALE - SOMMER XP707

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-18 21:08:37 UTC
From: Jos&#65533; Lopes <fartolopes@mail.telepac.pt>
Message-ID: <426421e9$0$27142$a729d347@news.telepac.pt>
Source record: 78853

I am interested to sale my hf antenna above mentioned that is in very good conditions.

Reason: need to renew and create a new set up of antennas.

Antenna: Sommer (DJ2UT Beam)
Model: XP 707
Bands: 10, 12, 15, 17, 20, 30 and 40 meters
Balun: The balun furnished with the Sommer antennas is a low-loss air core type using RG142 (BU) Teflon cable. The balun will handle 2.9 kW continuous output at 30 MHz with a loss of only 0.05 dB.
This antenna it still on my tower and working very well.
For price please send one email to:
fartolopes@mail.telepac.pt

The transports costs will be at the resposability of the buyer.
If you are interestes we can sed some actual pictures, and for all the informations concerning gain and front/back, please go to the oficial site:
http://www.sommerantennas.com/beaminfo.html

From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <d4190v$44a$1@titan.btinternet.com>
Source record: 78854

New program. COAXTUNE.exe

A 1/4-wave coaxial line, short-circuit at one end,
behaves as a screened LCR tuned circuit. A line less than
1/4-wavelength, in parallel with a variable capacitor, behaves as an
adjustable tuned circuit.

For given line length, inner and outer diameters, the program
calculates the value of the tuning capacitor needed to resonate the
circuit at any frequency from LF to microwaves. Included in results
are line input resistance at resonance, input reactance (which is
tuned out by the capacitor), Q and bandwidth. Along with other
characteristics of the line such as Zo and attenuation.

Download program COAXTUNE in a few seconds from website below and run
immediately.

What is the URL for the Windows Simpfeed program link?
I don't see it on your web page. (Do you remember I
sent you a DOS BASIC program about a decade ago that
does that calculation without needing Rm and Xm?)

The Outbacker is a little worse than the Hustlers and a
little better than the Hamsticks on 75m - about 8 dB down
from a good bugcatcher or screwdriver.

994. Am I wasting my time? Maybe...

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-18 23:51:30 UTC
From: Ken Bessler <kg0wx@NOSPAMyahoo.com>
Message-ID: <6KX8e.3022$mS1.234@okepread04>
Source record: 78859

I'm trying for WAS from the center of the US
(EM17) with a trap 75/160m dipole up 20'
flat, pointed N/S and 100w SSB.

In just 1 winter season, operating very casually,
I've managed 45 states on 160 alone. I've operated
maybe 20 hours total.

My question is this: Should I even attempt 160 WAS
and try to get HI and AK or am I not being realistic
considering my setup? I never hear them!

Just wondering.... I could easily get the rest of
the WAS states on 40 or 80, probably in 1
weekend.

i am not clear on how this antenna would look, when i think of 2
elements "" phased or simul driven i presumed it would sorta look like
a typical beam elements in parrallel spaced apart

that being the case , i am not clear on how changing the feedpoint
alters the ew ns direction

unless of course the antenna is like a cross

the gain seemed nice wouldn't mind trying one, my catch is i am using a
sgc tuner to feed my present dipole, i suppose i could just take it's
output and feed both 'elements' be a neet experiment

thanks

For all practical purposes--germs, indeed, DID NOT exist before we
discovered them...
However, what have we learned from that mistake? Did we learn NOT to
dismiss possibilities too quickly (long before germs were found some
suggested the possibility)--I think this whole thread confirms that we DID
NOT!

Another question would be "Why would you NOT try?".

Don't think of your low antenna throwing off a blob of signal at only a high angle. It is throwing off signal at many angles. Your signal is just weaker at the lower angles.

> Just wondering.... I could easily get the rest of

This isn't a newsgroup for amateur, fundamentalist theologians.
I expect there are groups that will be glad to let you display
as much ignorance as you want. Go to them. The fundamental objection to
this thread, besides its irrelevance, is the boring, sophomoric
shallowness of the posts. You're just not interesting. If you persist
in spamming the newsgroup with unnecessary, philosophical claptrap,
prepare to be criticized.

Fred, again, thanks for these comments. A 75M broadband biconical antenna is apparently just what fits my needs and "tree configuration".

Question for you: The QST article does not address whether or not the two dipoles are cut to different frequencies, as you suggested for your personal situation you had. Do you think two exact length dipole lengths are what the QST article author was talking about, or are two different lengths necessary?

All I am trying to accomplish is put a a full size 75M dipole between two tall trees (will be about 50' or 60' high dipole) and to have an SWR across the band that does not exceed about 3:1 .

Cecil Moore, W5DXP wrote:
"Years ago I experimented with two-element beams where both elements were driven."

J.D. Kraus, inventor of the W8JK beam obviously did too. He found the most gain he could get is the configuration of the W8JK. Some of his results are summarized in Table 6-2 on page 192 of the 3rd edition of "Antennas".Cecil has this book, I believe. Kraus reports the W8JK gain as 6.1 dBi.

The W8JK has two dipoles spaced at 1/8 wavelength and fed 180-degrees out of phase. Close coupling causes super gain but a very low drivepoint resistance. Kraus calculates the drivepoint impedance as 9+j48 ohms on page 186.

Best regards, Richard Harrison, KB5WZI

The W8JK doesn't provide the most gain of any two element array of half wavelength elements for a given spacing. At 0.1 wavelength spacing, a two element array fed with a 166 degree relative phase angle provides about 1.4 dB greater gain than a W8JK. At 0.25 wavelength spacing, 142 degree phasing gives the highest gain, just over 1 dB greater than a W8JK. These phasings also provide a higher feedpoint impedance than the W8JK, which results in decreased conductor loss and easier matching.

The W8JK has some advantages over other two element arrays, but having the highest gain isn't one of them.

Dear all,

Mrs. yin,SV7DMC and Mr. pez,SV7BAX of TheDAG are strongly suggested your newsgroup, to ask for support, help, comments or opinions about antennas matters. I want to give the name "Dim Diamond" to a prototype antenna which I will examine theoritically and propably construct later. I just want to know if there is such a name already assigned to another antenna.

Thank you in advance for your time

Hi
I have HI and AK on 160m too, from Pennsylvania with a 200' loaded dipole
thats 35' at the center and 15' at the ends and a 100w. I don't hear them
often but contests are the best times to look for the rarer states as the
big contest stations are on and you can take advantage of there superior
antennas and operating skill to hear you.
But a big help is if you can put up some sort of a receive only antenna. It
makes DX on the low band much more fun.

Roy, W7EL wrote:
"The W8JK doesn`t provide thye most gain of any two element array of
half wavelength elements for a given spacing."

The W8JK had the highest gain of the 5 examples compared in the table.

The advantage of EZNEC is shown in Roy`s posting.

Roy also wrote:
"At 0.25 wavelength spacing, 142 degree phasing gives the highest gain,
just over 1 dB greater than a W8JK. These phasings also provide a higher
nfeedpoint impedance than a W8JK,---."

I`d rather have Roy`s antenna.

Best regards, Richard Harrison, KB5WZI

Chuck, 120 degrees of the included angle of a dipole (fanned underneath a horizontal, or installed as an inverted-vee by itself) was described in this forum as the minimum recommended angle for optimal performance. I'm sorry I can't locate a file I probably saved that information in, but it is a number that the originator in this group might recognize as his suggestion ;-)

Not sure of DIM DIAMOND, but there IS a "Diamond" Antenna company. Some may view your name as a part of that company and mistake your product as one of theirs. The company itself may feel it is a slam against one of their products - being that "dim" here means weak - among other things. It "could" prompt legal action being the names are similar or enough to create confusion. A lawyer in business practices could further advise. Not sure why you named your antenna "DIM" diamond, but you may want to reconsider.

I don't know the model numbers of the "Diamond" antennas, but I'll put up a for instance using a fictitious model name and number to show how confusing it could be.

The "Diamond" antenna company has a Diamond ATC - 12 - HF antenna laying claim to give 7dB gain. Then someone would see the "Dim - Diamond" which is an H.F. antenna boasting 3 dB gain. The name could very well be confusing. Someone could very easily think your antenna is being sold by the "Diamond" company.

Just my 2 cents.

ml wrote:
> that being the case , i am not clear on how changing the feedpoint
> alters the ew ns direction

Referring to the files I attached yesterday:
If the current in element#2 lags the current in element#1
then you get 12 dBi gain in one direction. If the current
in element#2 leads the current in element#1 then you get
12 dBi gain in the opposite direction. The phasing feedline
might look something like this with coaxial 'T' connectors
installed at points "x" and 'y':

Element#1--------x----------y--------Element#2

Assuming connecting the RF at point 'x' will yield 12 dBi
gain in a Westward direction, connecting the RF at point
'y' will yield 12 dBi gain in an Eastward direction
without moving the elements.

==========

Slighty change the lettering. eg., "DIMOND-1"
One word and fewer characters.
It's more business-like and more eye-catching.
The number implies an engineering background.
Your "Dim" implies a mental deficiency.
Still retains a strong allusion to a diamond shape.
Extremely unlikely it has already been used by anyone else.
For successive prototypes or versions use -2, -3, -4 etc.
Be confident. Anticipate its successful future.

I promise not to use it for MY next revolutionary invention.
No charge for this small service. ;o)

A person asserting such a thing obviously believes in
primacy of consciousness, i.e. whatever the person
believes with the faith of a grain of mustard, then
the belief has to be true and one can move mountains
with one's mind if one only has enough faith.

OTOH, some people believe
in primacy of existence, i.e. existence exists and
is what it is no matter what a person believes. The
first argument I know of between those two sides
occurred between Plato and Aristotle and hasn't yet
been resolved.

Where your simpfeed method really makes sense is with beams
where the elements are more than 1/2WL long. For instance,
attached is the 33 ft. long, two-driven-elements spaced at
ten feet used on 17m. The impedances are high enough to use
300 ohm twinlead for the phasing and the feedpoint impedance
at the phasing harness is around 25 ohms.

Roy, what is the secret to balancing those currents in the
two elements? With the same Z0 phasing lines, the SWR circles
don't intersect so the impedances looking into those phasing
lines is never equal. Does my question make sense?

"Dim" might not be a good choice for English-speakers.
Applied to EM waves, it means "weak".

A biconal has all the legs the same length. I varied the lengths to see if I could get by with less than 15 feet. It was not successful. A biconal cage however gets really wide. Less than 2:1 from 3.5 to 4.

As an aside, anecdotally the cage and biconal are both quieter than a dipole.

Warmest regards from John? Must be a relay.

It's probably more efficient just to set the message filters to ignore posts originating from particular email addresses. That still allows the choice to read the more reasonable viewpoints offered in any given thread, and vastly improves the overall signal to noise ratio.

Interesting to note that of the few addresses that I've chosen to filter on a newsgroup, all have been for people who happen to use a phoney alias. I detect a correlation.

Source record: 78790

The method is described briefly in the article posted on my web site.

If someone gives you the self and mutual impedances of two elements and the lengths of two feedlines connecting them to a common point, it's a fairly simple matter to calculate the resulting element currents. What the program does is work the same problem backward. That is, given the self and mutual impedances of the elements (or in the case of the new program, the feedpoint impedances when properly fed), it finds the feedline lengths which will produce the desired current ratio *in those two impedances*. Years ago I got interested in the problem and figured out how to work it in that direction. It involves a bunch of variable transformations to keep the equation sizes reasonable, and results in a nice, closed-form solution. Some time after I came up with the method, I spotted an article in Ham Radio magazine which described a solution using an iterative approach -- it solved the problem in the easy direction, looked at the result, modified the feedline lengths, tried again, and so forth. That works (I had done it that way before figuring out the closed form solution), but can be time consuming -- at least it could with the computers of the time --, and you have to be careful with the algorithm to keep the process stable.

I wrote to the author of the Ham Radio article telling him of my method, and he suggested that I write it up. I had just gone through a lengthy period of very unpleasant dealings with magazines and editors (particularly Rich Rosen at Ham Radio), and had no interest in having more of it. So he ended up writing the paper describing the method in step-by-step fashion. You can find it in "A Voltage-Matching Method for Feeding Two-Tower Arrays" by A. Christman, in IEEE Trans. on Broadcasting, June 1987. Or if you're a masochist, you can try untangling the GWBASIC spaghetti code in the original DOS programs.

But a big help is if you can put up some sort of a receive only
antenna. It
makes DX on the low band much more fun. ....

Also...Would probably have more luck on the transmit end,
using some type of vertical. 20 ft high is pretty low for a 160
dipole...Makes long haul DX not for the faint of heart...
But....It can be done with a low wire, if the band is *real* quiet...
I remember back when I first started working 160 , I worked
HI three times in one winter, using just a 80m dipole fed like
a vertical from the shack, and about 120w. But it was quiet
that year, and my antenna was more like 36 ft high instead
of 20...Might try feeding that dipole like a vertical on 160m, just
as a test...Might surprise you...I bet on long haul, it does better
shorted, and fed like a vertical, than when running it normally...
You can compare just on receive to tell which would be best..
The DX will be history soon on 160, except for those with super
receive antennas...The noise is coming back up slowly...
You may have to wait till next winter unless you get lucky and
get some more quiet nights before summer...:/ MK

1027. Re: Two Element Beams

Newsgroup: rec.radio.amateur.antenna

Source record: 78792

There are a couple of distinct advantages of the W8JK over the antennas I described. One is that it can be fed with two equal lengths of transmission line to the elements, one being given a physical half twist to effect the phase reversal. Then you have an antenna whose properties remain the same over an extremely wide bandwidth. The second is that the free-space pattern consists of two relatively narrow lobes in the vertical plane, with an overhead null. This results in a concentration of radiation at lower angles than you'll get with a typical Yagi or most other two element horizontal antennas.

The tradeoffs are that because of the bidirectional pattern, half the radiation doesn't do you any good; there's no front-back ratio (although it's also poor on the maximum-gain antennas I described); and loss has to be managed and can potentially be a problem because of the low feedpoint impedances.

There's no single perfect antenna -- you pays your money and you makes your choice. As Richard Heinlein so succinctly said, TANSTAAFL.

I got the impression that the OP was planning on giving a name to an antenna design, like "windom" or "G5RV," not a particular commercial product. I don't think it would infringe on anyone's trademarks in that case. He's probably concerned more about avoiding the confusion of duplicating someone's existing name.

The trademark protects businesses like Diamond Antenna from other people using similar names or marks to derive sales from their presumably hard-earned reputation. If people could potentially become confused by the name "Dim Diamond" and spend money on you, even if you're not competing with Diamond, then Diamond are legally obligated to take action against your use of their name.

If you are just naming the antenna design and publishing construction notes, there is not a great likelihood of confusion; it's harder to confuse constructing your own antenna with purchasing someone else's. Therefore there's not much likelihood of upsetting anyone at Diamond.

Besides, some trademark holders must necessarily be less agressive. You wouldn't expect Neil Diamond and the De Beers company to come after you.

Oh yeah..

>> The number implies an engineering background.

I'm proud to say that this marketing gag doesn't work on me, and I hope it doesn't work on many other hams. At least the name "Joey" tells you it's from Australia and comes in a pouch.

Don't know what it means, but a Google search brings up a musical
group by the name of Dim Diamond, playing in the Brooklyn area.

Given the wind potential here, along with loading on my antenna support lines, I probably should go with the biconical dipole over a cage. I do have plenty of room to do a 15' end spacing, though.

> As an aside, anecdotally the cage and biconal are both quieter than a
> dipole.
>

I hadn't seen any reference to noise benefits from a biconical, so that's nice to hear! Thanks for the info.

The reason some people don't know for sure if they are going to Heaven when they die is because they just don't know.

The good news is that you can know for sure that you are going to Heaven which is described in the Holy Bible as a beautiful place with no death, sorrow, sickness or pain.

God tells us in the Holy Bible how simple it is to be saved so that we can live forever with Him in Heaven.

"For if you confess with your mouth Jesus is Lord and believe in your heart that God raised Him from the dead, you WILL BE SAVED." (Romans 10:9)

Over 2000 years ago God came from Heaven to earth in the person of Jesus Christ to shed His blood and die on a cross to pay our sin debt in full.

Jesus Christ was born in Israel supernaturally to a virgin Jewish woman named Mary and lived a sinless life for thirty-three years.

At the age of thirty-three Jesus was scourged and had a crown of thorns pressed onto His head then Jesus was crucified.

Three days after Jesus died on a cross and was placed in a grave Jesus rose from the dead as Jesus said would happen before Jesus died.

If someone tells you that they are going to die and in three days come back to life

again and it happens then this person must be the real deal.

Jesus Christ is the only person that ever lived a perfect sinless life.

This is why Jesus is able to cover our sins(misdeeds) with His own blood because Jesus is sinless.

The Holy Bible says, "In Him(Jesus) we have redemption through His blood, the forgiveness of sins..." (Ephesians 1:7)

If you would like God to forgive you of your past, present and future sins just ask Jesus Christ to be your Lord and Saviour.

It doesn't matter how old you are or how many bad things that you have done in your life including lying and stealing all the way up to murder.

Just pray the prayer below with your mouth and mean it from your heart and God will hear you and save you.

Dear Jesus Christ, I want to be saved so that I can have a home in Heaven with You when I die. I agree with You that I am a sinner. I believe that You love me and want to save me. I believe that You bled and died on the cross to pay the penalty for my sins and that You rose from the dead. Please forgive my sins and come into my heart and be my Lord and Saviour. Thanks Lord Jesus Christ for forgiving me and saving me through Your merciful grace. Amen.

Welcome to the family of God if you just allowed God to save you. Now you are a real Christian and you can know for sure that you will live in Heaven forever when this life comes to an end.

As a child of God we are to avoid sin(wrongdoing), but if you do sin the Holy Bible says, "My dear children, I write this to you so that you will not sin. But if anybody does sin, we have one who speaks to the Father in our defense Jesus

Christ, the Righteous One."

Those of you that have not yet decided to
place your trust in the Lord Jesus Christ
may never get another chance to do so
because you do not know when you will die.

Jesus said "I am the way, the truth and
the life: no one can come to the
Father(God)(in Heaven), but by me."
(John 14:6)

This means that if you die without
trusting in Jesus Christ as your Lord and
Saviour you will be forever separated from
the love of God in a place called Hell.

The Holy Bible descibes Hell as a place of
eternal torment, suffering, pain and agony
for all those who have rejected Jesus Christ.

The good news is that you can avoid Hell by
allowing Jesus Christ to save you today.
Only then will you have true peace in your
life knowing that no matter what happens you
are on your way to Heaven.

Praise the Lord!
Servant of the Lord Jesus Christ
Ronald L. Grossi

*Show this to your family and friends so
they can know that they have a choice
where they will spend eternity. Thanks!

Source record: 78804

A few days ago I did a range check between
my base and handheld on 445 mhz and noted
the spot where I started to loose comms.

I came home and calculated xmtr power, feedline
losses & antenna gain. I figured I had about 114.4
watts ERP. I changed to 147.555 and re did the
test. Despite the fact that I figured I had 187.7 w
erp on VHF, I started loosing signal at the same
spot.

Base rig is a FT-857D, Handheld is a VX-7R with
the stock antenna. Base antenna is a Comet GP-6
up at 40' fed with Flexi 4xl coax. Terrain is flat.

Based on my data, either:

A) The difference in ERP is too small to matter, esp.
when you figure in UHF's higher path loss.

or

B) I need to do tests on both freqs at more than 1
location to establish a coverage pattern.

What do you guys think? A, B or ?

Sorry for the cross posts. I'm trying to locate someone.

I'm looking for a ham living in Calgary who was going to align my
Heathkit SB-401/SB-303 combo last year (or was it two years ago?). I
lost the email address and phone number --- everything. He mentioned he
could also align my Cardon "Spitfire" as well (if that rings a bell).
I'd like to ship the pair off for alignment now that it's warm weather.

Also, if there is anyone else who can do this, please contact me in case
I can't find the above person.

Thanks very much.

Noting the precision of your wattage calculations, I should have been more
specific in my answer in the previous message.
d(mi)=1.415 * sqrt antenna height in feet
so to get you down to the decimals 8.9492457782765135095568687307446 miles
This distance could be reduced by objects between you and your antenna.
```

a rule of thumb is sqrt 2* sqrt antenna height in feet = distance in miles.

Whew. I'm glad you amended your remarks Fred. I was beginning to
worry about you.

Now, suppose there is a single deciduous tree located precisely half
way between the two points. Can you calculate whether it is leafed
out or not based on the added path loss?

Show your work [g].

What would happen if you isolated that second driven element from the boom
(the one you are effecting the phase-shift in, and added another reflector
(naturally it is in proper phase) behind it? Could you get the best of two
worlds? The advantage of the phase-shift plus a FB ratio?

G3HCT (now VK4OQ) used this system for 40m. By phasing any pair you have a choice of six 2-element beams, with the third element inactive (open-circuit).

The gain is about 1.5dB lower than a four-square, comparing both beams in their best (forward) direction, but the triangle has more directions to choose from, so in some directions it's actually ahead of the 4sq.

The verticals were quite closely-spaced, and phased to give *two* rearward nulls at around +/-120deg. That gave a total of 12 switchable nulls on receive, which can be very important in European QRM.

Ok, forget the fact that the word "Diamond" is in the name being proposed.
The word "DIM" in itself leaves a lot to be desired. Many may take a less
than positive view on it. Dim - in and of itself - doesn't sound good - in
reference to any sort of "product". That "Dim" antenna - may just get a
"dim" review. Lots of luck trying to sell that! A "dim" diamond - less than
lustrous! I don't know... to me, it spells out "poor" quality - just in the
name. Were it mine, I'd use anything other than "dim". But, to each his
own.......

1059. Trying to build an antenna for cell phone

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-20 11:56:21 UTC
From: vile5@comcast.net
Message-ID: <1113998181.550765.184160@l41g2000cwc.googlegroups.com>
Source record: 78824

Thought I would start here for this question. I would like to build a passive antenna for my cell phone that has no port. I know it goes into the 1100 MHZ range if that helps. I would like to use this for using in my house and for car use. Unless you know of a good link to a site that sells such a thing. It seems like every new cell phone I get over the years never has the range that is needed to pick up the towers in my home (upstairs) or in my car over country roads (drops calls).

Thanks

OK, I'll inject some.
I check into the Spiderweb Net mornings on 14.347.
My 4-element SteppIR is too directional to copy the boys in Bogota and
the New Jersey crowd from my hill in Texas without swinging the beam back
and forth.
The solution is to simply retract the directors and use the antenna as a
two-element beam.
I just point it at South Florida.

Thanks,

That was the only 6 meter beacon I could hear. I knew/know that the
one beacon wouldn't be a good sample but I was/am still surprised that
the difference was 1/2 scale on the radio. It went from scratchy to
full quieting and full scale. I didn't spend much time on it as my
objective was to trim the antenna for ten meters.

It is interesting though.

1070. 3/2 wave dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-20 15:06:38 UTC
From: Buck <iam@this.site>
Message-ID: <merc61tkrf5m3sqkdh35i4g425hnmb3tme@4ax.com>
Source record: 78631

Probably my first HF antenna as a novice was a 40/15 meter dipole where 40 meters was 1/2 wave and 15 was 3/2 wave. I have never had a problem dropping SWR on 15 meters to 1:1.1 with this antenna center fed. However, as I understand antenna radiation on a wire, the optimum point should be somewhere else along the wire to match the impedance properly. I suspect it should be close to 1/3 of the way from one end.

Any thoughts about this?

Working AK7/KH6 will take time as you need to be on, have propagation
and have those stations on at the same time. If you picked up 45
states in 20 hours on 160, you may want to continue looking for your
remaining states on 160 while taking time to start your WAS on 75/80.

As for the antenna, I don't know how much loss there is, but usually
there is a noticeable difference between a regular loaded dipole and a
dipole with a trap. A full sized dipole will be best, if you have the
room. Additionally, look towards re-orienting the antenna for maximum
lobe in the direction of the states you need.

Just a few thoughts.

Sometimes these things take time. Some people work all states in a
weekend, usually during a contest, but sometimes it takes time.

Good luck

> in a coma.

That may or may not be true.
But Christ was not in a coma: He was dead.
1) He died from asphyxiation from the extreme position His Body was placed in by the sufferings of the Cross.
2) His Heart was pierced with a spear by a Roman soldier who was standing by, to confirm His Death. Both red Blood and Serum were seen escaping from the Wound in His side. If the asphyxiation did not kill Him, surely the spear through His Heart did.
3) Christ announced His impending Death loudly before He expired.
4) Christ told many eye-witnesses that He would die.
5) John the Apostle was an eye-witness to His death on the Cross, as were His Mother and Mary Magdalene, and perhaps also St. Peter.

Not only did Christ die, He was raised from the dead within three days of His Death, as predicted by the Prophets of the Old Testament period.

1) That He was raised from the dead was witnessed personally by all His closest friends, who give their testimony in the New Testament, along with over 500 other disciples.
2) He was on the Earth for 40 days before He ascended to Heaven, teaching the Apostles and encouraging them for the trouble ahead, as witnessed by at least 200 disciples, including His Mother, John, Peter, Mark, and several of the other disciples.

3) He predicted His Death and Resurrection for 3.5 years, while He was ministering among the people of Israel and teaching them the facts of the Kingdom of Heaven.
4) This fact was testified to by Matthew, Mark, Luke, and John. While St. Luke was a witness after the fact, Matthew, Mark, and John were all eye-witnesses, and give their testimony in the Gospels called by their names.
5) The facts of His Resurrection have been testified to for almost 2000 years, by His Church, which He founded during His Lifetime.
6) The facts of His death and Resurrection have been testified to for almost 2000 years, by His close friends at first, then by billions of others who have experienced His Presence with them through the Holy Spirit. While this Church has had its ups and downs during this 2000 year period, its central teachings have been clearly taught for this 2000 years, and will continue to be taught for the next two thousand, if Christ does not return soon, as He promises His followers.
7) This Church, along with all other Orthodox Christian churches, currently has over 1.2 billion members, and is on every continent of the Earth, keeping the societies it lives among from totally destroying themselves through their own wickedness.
8) This Church has endured the persecutions of the Jews when she first started after Christ departed to return to His Father, as He predicted during His Lifetime, and as testified to by the 4 Gospels and in St. Paul's letters.
9) This Church has endured the persecutions of many others since, but the Holy Spirit has turned the Church strong through her persecutions.
10) This Church started out as a small (200+ members) group of frightened men and women, but had conquered the Roman world by the time of St. Constantine, in the 4th Century. The Roman Empire was conquered by her prayers and teachings, not knives and swords.
11) This Church now conquers the hearts and minds of others, through prayer and Orthodox teaching, and the sacrifices of her Bishops and Shephards.
12) Nothing her detractors do can keep her from fulfilling her destiny as the Witness of Christ's sufferings and triumph until He returns, as He promised.
13) What Christ spoke to the world, and His disciples, was the Word of God. He still speaks this Word through His Church, even today, tomorrow, and forever. Not a Word He spoke will fall to the ground. They will all be accomplished, every Word He spoke.

If you pierce someone's heart, a dribble of blood and some "serum" would
seem a little understated.

> 3) Christ announced His impending Death loudly before He expired.

Hmmm, I annouce my impending death regularly.

> 4) Christ told many eye-witnesses that He would die.

Where are these euewitness's accounts?

> 5) John the Apostle was an eye-witness to His death on the Cross, as were

Er, are you talking about the chapters of the Christian Holy Book
attributed to them which the best moder scholarship places no earlier
than 50 or so years after the purported events, and which in their
modern form date to the early 3rd century CE?

> 5) The facts of His Resurrection have been testified to for almost 2000

Wickedness, like telling Africans that Condoms don't stop HIV/AIDS? Like
covering up pedophilia? Like murdering followers of other religions?

> 8) This Church has endured the persecutions of the Jews when she first
> started after Christ departed to return to His Father, as He predicted
> during His Lifetime, and as testified to by the 4 Gospels and in St. Paul's
> letters.

Didn't the Catholic Church agree that they had been mistaken about the
collective guilt of the Jews?

> 9) This Church has endured the persecutions of many others since, but the
> Holy Spirit has turned the Church strong through her persecutions.

The "church" (How many different Abrahamic Faiths draw on the New
Testament as a source document, including Islam?) has a pretty good
track record of persecution of other faiths even in the last few weeks.

> 10) This Church started out as a small (200+ members) group of frightened

I thought Christ spoke to the Jews and some nutcase called Paul saw the
potential in spreading it to the Gentiles, of course I did make the
mistake of reading the Bible... You should try it.

...Brock.

I have thanks. I'm just not sure of the elevation results.

1086. UV Resistant Insulated Wire for G5RV ?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-20 18:34:04 UTC
From: Gary
Message-ID: <op7d6117bb6d6ghj5hoajmijkdibnnmg8o@4ax.com>
Source record: 78649

I thinking of homebrewing a G5RV and the way it will have to run across my property between two trees it's going to touch some small branches and/or some leaves. I can buy inuslated wire at Home Depot or Lowes but a friend mentioned it wasn't UV protected and the insulation would eventually falll off. How about enameled wire ? Maybe there's another wire type etc I haven't thought of ?

Thanks in advance

73 Gary K8IQ

1087. Re: UV Resistant Insulated Wire for G5RV ?

Newsgroup: rec.radio.amateur.antenna

Message-ID: <116d975d4tli850@corp.supernews.com>
Source record: 78650

Gary, I had a multi-band dipole antenna (4 dipoles off one feedline) up for over 20 years and it was made from #14 AWG electrical wire right off the spool that my electrician neighbor had on his truck. There was no uv protection and the covering was still on the wire when I took it down.

>
> Any thoughts about this?

Think about it. There would be three current maximum points
on a 3/2WL wire. These three current maximum points correspond
to the low impedance feedpoints on the antenna. They would be
at 1/6, 1/2, & 5/6 from the ends. 1/3 from the end of a 3/2WL
would be a high impedance point, i.e. not a good feedpoint.

He was supposed to be a tough hombre. Why did he die so quickly
compared to others who had been crucified? Why didn't his legs
have to be broken? Maybe because he was drugged?

> 2) His Heart was pierced with a spear by a Roman soldier who was standing
> by, to confirm His Death. Both red Blood and Serum were seen escaping from
> the Wound in His side. If the asphyxiation did not kill Him, surely the
> spear through His Heart did.

Absolutely nothing said about a "spear through His *heart".
Many present day people have survived knives and spears in
his/her *side*, including yours truly.

> 3) Christ announced His impending Death loudly before He expired.

All Jesus said was, "It is finished" and placed his spirit in
the hands of God. And it was finished because of the knock-out
drugs He had just received in the vinegar. (I feel that way
after a couple of Xanax.)

> 4) Christ told many eye-witnesses that He would die.

Of course, all part of the "Passover Plot".

> 5) John the Apostle was an eye-witness to His death on the Cross, as were
> His Mother and Mary Magdalene, and perhaps also St. Peter.

Who slipped Him the knock-out drops in the vinegar?

> Not only did Christ die, He was raised from the dead within three days of
> His Death, as predicted by the Prophets of the Old Testament period.

Only the illusion of death was necessary.

> 2) He was on the Earth for 40 days before He ascended to Heaven, ...

Nope, he then went to America and preached to the Indians, according
to the Morman prophets.

I am planing on side mounting a 2 meter J-Pole part way up on a tower.
How far from the tower should I mount the antenna? I do plan on making
the final adjustment of the feed point with the antenna mounted up a few
feet on the tower. The radiation pattern is not a big concern. In fact
I would prefer that it favor one quadrant.

Thanks for any advice.

I've seen insulation fall off 70-year-old AC power cords, but never
off antenna wire. My Lowe's wire has nylon insulation -- looks and
feels sturdy even after exposure to the elements -- The Wireman sells
wire with UV-resistant PVC insulation, but I wouldn't buy it just for
that.

Gary,
Depending on the type of wire/insulation you use, the insulation can certainly come off. Forgot the name of it but it usually has a color coat then a clear insulation. The clear insulation does come off, looks like a snake shedding it's skin. The color insulation (under the clear stuff) hasn't come off yet, but it's only been up about 10 years. The antenna does run through trees and I'm sure some of the insulation has rubbed off. It doesn't seem to affect things, so I don't really care...

Source record: 78663

The program you're referring to is probably Brian's TA (Terrain Analysis). It gives you the antenna pattern over an arbitrarily shaped ground -- I've used it for many years in choosing Field Day antenna locations. It's a DOS program, but I don't know of any more recent program that does the same thing. I believe Brian will still sell it if you contact him by mail at his Callbook address.

TA requires as its input a free-space pattern in the OpenPF format he devised (with some help and advice from me). EZNEC and Brian's analysis programs like AO produce plot files in that format. It's thoroughly documented in the EZNEC manual, so it wouldn't be difficult for someone with minimal to moderate programming skills to convert files of other formats to OpenPF for use by TA.

For the OP, though, if the ground is simply constantly sloping for a long distance, do as suggested -- tilt the antenna in the model. Then tilt the resulting pattern in the opposite direction to see the result.

Hi Doc
That clear coating is nylon, and I think what you're talking about is wire rated as "THHN".
The nylon makes it easier to pull through conduit, and gives some additional mechanical protection.
You're right - the nylon part does flake off a a bit after some time in the sun, but the pvc underneath it stays on pretty good.
If you have some 'romex' (or type NM) cable (like 14-2wg) - you have something different you can work with.
If you strip off the outer jacket of the romex (nm cable) you'll have 3 separate solid (not stranded) wires inside - two are insulated (one black and the other white) - and one bare wire (the ground).
The black and white wire from this romex does not have the nylon coating - and so will not flake off. This romex usually comes in 250-ft coils at Lowe's and such places. The THHN wire (which is very usable, by the way) usually comes in 500-ft spools - and is available is stranded and solid conductors, in a variety of colors.

If one can find someone from a nearby railroad, (or a crew
removeing Railroad Signal lines), it is possible to get
Insulated Wire for antennas for Free, or little cost, as
the Railroads signals are going to Point-Multi-point
radio control. Two caviats: 1) the stuff is hell for
stout (#9, or GREATER), and 2), is Copperweld. But,
if you can obtain it (and the scrap value is such, that the
railroads either gave it away, or sold it for the value
of the poles that support it), the only way it will come
down is when your support structure fails! And, yes,
the old "Code Line" wires (at least on the old S.P. lines)
was insulated- some over 40 years old, and you cant get the
insulation off, without burning the wire in a fire!
Have also obtained it in derailments in the past- and
stout enuff to tow a trailer with ! as info, Jim

Interesting John, that's faster than I could do a CD's worth in our data center in the ISP I work at, and that would mean knocking all our legit traffic out. I have a DS3 plus a bunch coming in from another provider on 100M ethernet. What kind of service do you have anyway?

Source record: 78674

Ron, K0QVF wrote:
"How far from the tower should I mount the antenna?"

Supposing you want the least effect on the pattern and impedance, place the antenna as far as possible from the tower.. Satisfaction is obtained with much closer spacing. The tower is non-resonant. Its reactance will impede induced current from a radiator which is really close by. If there is little induced current there is little re-radiated energy to foul the pattern.

The 3rd edition of Kraus` "Antennas" has a graph on page 350 of gain in field intensity versus spacing from a flat reflector. At 0.5 wavelength the gain is 0 dBi. That`s less than the resonant 1/2-wave antenna alone which has about 2.14 dB gain over an isotropic.

The graph shows a gain of about 2.14 dBi with a spacing of only 0.1 wavelength spacing. So, anything greater than 0.1 wavelength from the tower should be fine. That`s 20 cm in the 2-meter band, or about 8 inches. More distance means less coupling and should be better.

Best regards, Richard Harrison, KB5WZI

Yes, and I believe they occur 1/4-weave back from the open-circuit ends of the antenna and at the very center of the antenna.

The only way to get 0 dBi maximum gain from a lossless antenna is to have a perfectly circular pattern in all azimuths and elevations. It's not possible to have a maximum gain (that is, gain in the best direction) less than 0 dBi unless loss is present. This is something everyone with a basic understanding of antennas should know.

So it seemed to me very unlikely that a dipole spaced a half wavelength from a reflector would have a perfectly circular pattern and, therefore, it must have gain greater than 0 dBi in some direction. I don't have Kraus' third edition (yet), but there's a diagram on p. 546 of the second edition which I suspect is the same as the one Richard is referring to. The caption under the graph clearly says that the gain at 0.5 wavelength is 0 dB *relative to a half wave dipole in free space*, or about 2.15 dBi, not 0 dBi.

If the third edition really says that the gain of a half wave antenna spaced 0.5 wavelength from a reflector is 0 dBi, it's an error and should be brought to the editor's attention so it can be corrected.

I also believe that while you might draw some possible parallels, you can't directly apply the characteristics of an antenna in proximity to an infinite reflecting plane (as in Kraus) to those of an antenna in proximity to a tower.

The HFTA program included with the last two editions of the ARRL Antenna Book will do most of what TA does, and is a Windows program.

A unique feature of HFTA is that it not only calculates the vertical pattern over your real-life ground profile, but also shows how well that pattern agrees with the likely angles of arrival of signals from various parts of the world - which is, after all, what really matters.

The HFTA User Manual is available as a free download from:
http://www.arrl.org/notes/9043/hfta.pdf

The program itself is free if you've bought the book... which is highly recommended in its own right. Also, you really need the book to understand the concepts behind the program.

The manual includes a very long section detailing how US amateurs can tap into public-domain map databases, to generate detailed height profiles in selected radial directions around any arbitrary QTH.

The rest of us have to generate the terrain profiles using a paper map, ruler and Notepad. This is tedious, but poring over a detailed map can teach you a lot about your local geography, and the job only has to be done once (unless you're surveying several possible sites, as Roy was).

>documented in the EZNEC manual, so it wouldn't be difficult for someone
>with minimal to moderate programming skills to convert files of other
>formats to OpenPF for use by TA.

Unfortunately HFTA doesn't read OpenPF files. It only allows the choice of predefined vertical patterns for a dipole, or for generic "2-element", "3-element" and larger beams, or for stacks of beams.

This restriction isn't a huge problem, because the major features of your vertical pattern depend much more on the antenna height and the terrain profile than on the antenna itself. That means the "closest

generic" antenna pattern will give a very good approximation.

However, it would be nice if HFTA could read the vertical pattern of your or my favorite antenna, so that we could confirm that fact for ourselves.

Another acknowledged limitation is that both HFTA and TA can only be used for horizontally-polarized antennas. Doing the same for verticals would involve major complications about pseudo-Brewster angles... a very much larger can of worms.

Roy is gallantly trying to be non-commercial about this, so someone else had better say it:

Download the free demo version of any NEC-based antenna modeling program, and model the effects of the actual tower geometry. It's the only way to see what's really happening.

You'll get a good first approximation by modeling the tower as its three very long vertical legs. Since you're only interested in the effects of the tower on the J-pole's omnidirectional pattern, you can use any kind of vertical omni to model the antenna itself - a center-fed dipole for simplicity.

Thanks, That's what I was looking for. so I can use the antenna with 1/4 - 3/4 or center loaded.

Would the off-center setting create another resonant frequency for the antenna?

Assuming the antenna were cut for 1/2 wave at 7 MHz, it would operate on 21 MHz, but if off-center fed, would it also resonate on 20 MHz with the 1/4 wave element?

Thanks.

I have used the THHN wire for nearly 27 years. I have had no
problems. The outer clear plastic layer breaks up but does not affect
the antenna that I can notice. The colored plastic has never had a
problem. I have never left one up over a couple of years, but it has
always been good when I took them down.

I`m sure that`s it. I have Kraus` 1950 edition of "Antennas" and the identical groph is on page 327 in it.

If you look at the patterns of a 1/2-wavelength antenna at spacings of 1/4, 1/2, and 1/16 wavelengths spacing from a flat reflector nearby, they are all nearly circular, indicating little distortion in their unblocked direction.

Even less generally, one could think of the feedpoint in terms of
1/12-wave, 1/4-wave, or 1/2-wave from the end, depending on frequency.
But I'd be inclined to use 1/6 or 1/2 of the total length for fear of
brain fartage.

Some years ago, John Belrose VE2CV published an article in QST about off-center fed antennas, based on a combination of modeling and building. While they look attractive on a simulation program (where the feedline wasn't also modeled), he found that in practice it was very hard to keep the feedline common mode current down to a low value. The consequence of common mode current is that the feedline becomes part of the antenna, and that makes it very difficult to duplicate or to realize the idealized performance you might expect if you hadn't taken feedline radiation into account. Multiple current baluns should be able to reduce the common mode current to a reasonable value, but they'd have to be used unless you want a lot of feedline radiation and performance that's difficult to predict.

If I decide to put my screwdriver to use (I no longer mobile) up in the attic or on the roof, would radials about 8ft. be as good or better than a capacitave top hat?
Perhaps the large hats like DXEngineering has? That 8ft. comes from the old timers that say the radials should be as long as the physical height, I don't know 'nuff antenna math to really figure it out.

A bit more on the baluns Roy mentioned...

If the feedpoint is a high impedance (an even number of half-waves back from both ends of the antenna), it's difficult to get enough choke impedance to do much good if you put a single balun right at the feedpoint. It may end up being overkill, but if you don't have a good way to measure your line for antenna currents, you'll do well to put chokes about a quarter wave apart at the highest operating frequency. You want to avoid having a length of line between two chokes being a resonant half-wave long without anything in the middle to break up the resonance. So for operation on multiple bands covering a wide range, you should think about putting in three or more chokes.

Of course, if you put it up without any chokes and it does what you want, that's fine...just don't expect it will match the model of an isolated wire.

Cheers,
Tom

Chuckle Yes, they're nearly circular for close spacings (1/8 and 1/16 wavelength), but those aren't "circular patterns". The antenna isn't at the center of the circle -- it's on the circumference(*). I hope you're not seriously presenting this as evidence that the gain can be zero dBi.

The patterns and gains are, or should be, identical to those of half of a W8JK array with twice the spacing. For example, the pattern and gain of a dipole 1/8 wavelength above a perfect reflector is exactly the same as half the pattern of a W8JK array made of two of those dipoles spaced 1/4 wavelength. And those are far from an isotropic pattern.

(*) The patterns in the book also are circular because of the scale factor which was chosen. If some other scale factor were chosen, they wouldn't be circular. A truly circular pattern (one with the antenna at the center) is circular regardless of the scale. You can illustrate this with the EZNEC demo or standard program. Open the dipole1.EZ example file and click FF Plot to generate a 2D pattern. Notice that the two lobes are roughly circular in shape (with the antenna at the circumference, as in Kraus' diagrams). Leaving the 2D plot on the screen, in the main window Options menu, select 2D Plot Scale and choose Linear dB. Note how the shape of the two lobes changes. You can get a wide variety of shapes by changing the scale -- this technique is very useful to antenna manufacturers to make their beam lobes look extra narrow. In the main window, change the Plot Type to Elevation. Due to the orientation of the antenna, you'll now get a plot of the pattern looking end-on to the dipole. This will be a truly circular pattern. Click FF Plot to generate the pattern. Change the 2D Plot Scale back to ARRL Type and note that it remains circular. An isotropic antenna has a circular pattern like this regardless of the orientation; the 3D plot is a sphere. And that's the only antenna which can have a free space gain as low as 0 dBi when there's no loss.

Two different animals Butch, if you have a perfect ground under a short antenna, adding a capacity hat improves the antenna. With less than perfect it still helps. Reg has a program you can download that will show you the gains in efficiency at various hat sizes.

Mounted in the attic, I would put resonant radials for the higher bands where you have room. Once you have put the best counterpoise you can, add the capacity hat to improve efficiency.

It is always a trade off, if the hat is too big you won't be able to work 10. With the current direction of the sun spot cycle, I would try to get as efficient as I could for 20 and below. I would be inclined to string 3 wires, 2 cross corner and 1 end to end of the attic. Tie them together in the center and run a wire from the junction to the point you normally put the whip on the screwdriver.

Good luck and let us know what you did and your success with it.

I believe that all three people (Richard, Roy, and Fred) who have commented on this topic have misread the figure in Kraus. The gain at one-half wave spacing from the reflector is *zero*, not zero dB (relative to a dipole), nor zero dBi.

As expected from the simple mirror image model there is complete far field cancellation in the phi = 0, theta = 0 direction. That is the only direction referenced in the figure.

Message-ID: <116g66ac3ke809d@corp.supernews.com>
Source record: 78745

I have to apologize. I also misinterpreted the graph. The confusing graph is, in the Second Edition, Fig. 12-4 on p. 546. I've uploaded it temporarily to http://eznec.com/misc/Kraus2_Fig_12-4.JPG.

The caption says that the gain is relative to a half wave dipole in free space with the same power input. The numbers on the left side Y axis are the numerical gain, 0 to 3, relative to a dipole. 0 represents a numerical gain mulitplier of zero, or no field intensity at all. 1 is the gain of a half wave dipole in free space (about 2.15 dBi). A value of 2 represents a gain in field intensity by a factor of 2, or 6 dB relative to a dipole. The right hand side Y axis labels are the gain in dBi. Note that 2.1 dBi corresponds approximately with the value of 1.0 on the left side. The bottom horizontal line corresponds to zero field strength -- a gain of minus infinity dBi -- *not* zero dBi as Richard said, or zero dB relative to a dipole, which I initially assumed.

What I missed was that the gain is "in direction [phi] = 0", quoting from the caption. So this isn't a graph of the maximum gain, but the *gain in one specific direction* -- normal to the reflecting plane. At 0.5 wavelength spacing, the "gain in field intensity" (left set of Y axis labels) is a *factor* of zero, meaning that the field strength is zero, or minus infinity dBi. Sure enough, if you model the antenna, or two elements spaced one wavelength, you find that the pattern has a null directly broadside to the antenna ([phi] = 0). It has gain in other directions, but that's not what the graph is showing.

Of course, any lossless antenna has a gain of 0 dBi in some directions. In the case of the element and reflecting plane, the gain directly broadside to the antenna has a gain of 0 dBi at spacings of roughly 0.425 and 0.575 wavelengths. There's no particular significance to this -- the maximum gain is greater in other directions.

These gains and patterns can easily be seen with any modeling program, including the EZNEC demo, by modeling a dipole over perfect ground. You can also model two elements fed 180 degrees out of phase at twice the spacing and no ground and see that the pattern is identical except for being bidirectional.

Remember I said the current maximums would occur at 1/6,
1/2 (3/6), and 5/6 points? In a 3/2WL antenna, 1/6 is
1/4WL from the end.

Note that is 1/4WL which is 1/6 distance (16.67%) from
the ends. It is *NOT* 1/4 of the antenna. Hint: There are
six 1/4WLs in a 3/2WL antenna.

> Would the off-center setting create another resonant frequency for the
> antenna?

Nothing changes much. The radiation pattern will favor the
long side of the antenna. Since the currents are unbalanced
there may be an abundance of feedline radiation.

I vaguely remember the firewall/virus-protection needs to
be disabled during installation. I'm sure Roy will respond.

I could be wrong, and Roy will correct me if I am, but EZNEC seems to be written in Visual Basic, or similar... might you need the run-time libraries for an older edition?
And, he (Roy) mentions "double percision"--a nasty reality of basic (and some Fortran compilers also), which seems to confirm my suspicions...

Is that a DOS program? I recall upgrading to a Windows version, and think
it was 3.x.

Tam

1140. Good morning or good evening depending upon your location. I want to ask you the most important question of your life. Your joy or sorrow for all eternity depends upon your answer. The question is: Are you saved? It is not a question of how good you are, nor if you are a church member, but are you saved? Are you sure you will go to Heaven when you die? GOOGLE·NEWSGROUP·POST·146

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-22 00:00:20 UTC

Source record: 78756
Cross-posted to:
rec.radio.amateur.antenna,alt.sports.football.pro.tampabay-bucs,alt.tv.simpsons,news.software.readers,alt.fan.furry

The reason some people don't know for sure if they are going to Heaven when they die is because they just don't know.

The good news is that you can know for sure that you are going to Heaven which is described in the Holy Bible as a beautiful place with no death, sorrow, sickness or pain.

God tells us in the Holy Bible how simple it is to be saved so that we can live forever with Him in Heaven.

"For if you confess with your mouth Jesus is Lord and believe in your heart that God raised Him from the dead, you WILL BE SAVED." (Romans 10:9)

Over 2000 years ago God came from Heaven to earth in the person of Jesus Christ to shed His blood and die on a cross to pay our sin debt in full.

Jesus Christ was born in Israel supernaturally to a virgin Jewish woman named Mary and lived a sinless life for thirty-three years.

At the age of thirty-three Jesus was scourged and had a crown of thorns pressed onto His head then Jesus was crucified.

Three days after Jesus died on a cross and was placed in a grave Jesus rose from the dead as Jesus said would happen before Jesus died.

If someone tells you that they are going to die and in three days come back to life

again and it happens then this person must be the real deal.

Jesus Christ is the only person that ever lived a perfect sinless life.

This is why Jesus is able to cover our sins(misdeeds) with His own blood because Jesus is sinless.

The Holy Bible says, "In Him(Jesus) we have redemption through His blood, the forgiveness of sins..." (Ephesians 1:7)

If you would like God to forgive you of your past, present and future sins just ask Jesus Christ to be your Lord and Saviour.

It doesn't matter how old you are or how many bad things that you have done in your life including lying and stealing all the way up to murder.

Just pray the prayer below with your mouth and mean it from your heart and God will hear you and save you.

Dear Jesus Christ, I want to be saved so that I can have a home in Heaven with You when I die. I agree with You that I am a sinner. I believe that You love me and want to save me. I believe that You bled and died on the cross to pay the penalty for my sins and that You rose from the dead. Please forgive my sins and come into my heart and be my Lord and Saviour. Thanks Lord Jesus Christ for forgiving me and saving me through Your merciful grace. Amen.

Welcome to the family of God if you just allowed God to save you. Now you are a real Christian and you can know for sure that you will live in Heaven forever when this life comes to an end.

As a child of God we are to avoid sin(wrongdoing), but if you do sin the Holy Bible says, "My dear children, I write this to you so that you will not sin. But if anybody does sin, we have one who speaks to the Father in our defense Jesus

Christ, the Righteous One."

Those of you that have not yet decided to
place your trust in the Lord Jesus Christ
may never get another chance to do so
because you do not know when you will die.

Jesus said, "I am the way, the truth and
the life: no one can come to the
Father(God)(in Heaven), but by me."
(John 14:6)

This means that if you die without
trusting in Jesus Christ as your Lord and
Saviour you will be forever separated from
the love of God in a place called Hell.

The Holy Bible descibes Hell as a place of
eternal torment, suffering, pain and agony
for all those who have rejected Jesus Christ.

The good news is that you can avoid Hell by
allowing Jesus Christ to save you today.
Only then will you have true peace in your
life knowing that no matter what happens you
are on your way to Heaven.

Praise the Lord!
Servant of the Lord Jesus Christ
Ronald L. Grossi

No, I am wrong about that being a problem...
I should have looked first...
Here is another guy with a problem with EZNEC 2.0 on Windows XP--however,
not the same problem...
http://lists.contesting.com/pipermail/towertalk/2002-January/043902.html
So, it does run--with more or less success, on XP...
However, does setting the "compatibility option in the dos emulator of
Windows XP help with this problem? -- simply drop a cmd icon on your
desktop, right click the icon, pick properties, and set the "compatabiliy"
tab to windows 95 and run the program though this icon... might help....

That was a common problem with DOS EZNEC programs running on modern machines and the fix is simple. Drop me an email and I'll be glad to send you instructions.

Although I'm glad to answer questions here which are of general interest about EZNEC and its use, it's more appropriate to answer specific support questions directly.

> for an older edition?

No, that's not the problem -- it's due to DOS not being able to properly determine the size of a large amount of RAM. And the DOS versions were written with the MS BASIC Professional Development System, not Visual Basic. Windows versions of EZNEC (v. 3.0 and 4.0) are written in Visual Basic, except the calculating engines and a few speed-critical main program routines which are written in Fortran.

> And, he (Roy) mentions "double percision"--a nasty reality of basic (and
> some Fortran compilers also), which seems to confirm my suspicions...

Double precision isn't a "nasty reality" -- it's simply a way of storing floating point variables. Normal precision floating point variables are stored in four byte words, and consequently have a resolution of about seven significant decimal digits. Double precision variables require 8 bytes and have about 15 significant digits of resolution. Fortran additionally has a complex data type which requires twice as much storage space, since each variable of that type has two parts. Some compilers have additional, higher precisions available. The program author can choose which data type to use for each individual variable.

Yes, you are correct. In "C"/C++ conversion is automatic (or generates a compiler error prompting you to "cast" to another type) if there is the slightest chance you will unintentionally lose precision...
If I go to VB or Fortran I tend to get a lot of math errors (which are not caught by the compiler, but in real world use!) until I remember to compensate and control my code better... double precision is used by "C"/C++ (the "double"(integer) and "float"(floating point) variables) also (you are right, it is related to the size, in bytes(bits), of the math variable(s) in question), no problem--it is just more transparent in C.
And, you are correct again, "precision" is only a matter of where you wish to "quit", and "double-double-precsion" and greater are able to be done, either as a function of the compiler, hard code a routine directy in assembly language yourself, or the programmer can institute them in the high level code...
Visual Basic, Fortan, COBOL (yuck!), Pascal, "C", etc, etc are usually only a matter of syntax, style, speed and preference... "C" is just my personal preference...

Years ago it was common for Basic/VB to constantly have issues with math variables (actually, changes to the functions in the OS) in each new release of windows, I live in the past... <frown>

Warmest regards,
John

I normally use pieces of wood. In one end drill a hole to go over the mast. At the other end cut the center section out leaving two ends with the inside dimension slightly larger than the width of the ladderline insulator. Kind of a letter "U". Cover with spar varnish, at the mast end use a drywall screw through the piece of wood in to the mast. I normally predrill a 1/16" hole before putting in the screw.

On the "U" end the inside of the "U" should be just wide enough so the ends of the insulators on the ladder line fit snuggly into the "U". From one side of the "U" put a drywall screw and let it go through and just tight against the insulator to hold it in place. It is a lot easier to do than describe.

I normally mount mine at least 12" from the mast and use a board every 5 feet or so.

Just one solution, I am sure you will get many others.

Good Luck
Fred W4JLE

That posting is over three years old, and the poster has since upgraded to a Windows version. There are numerous possible problems in running DOS EZNEC under WinXP, and I've seen most of them more than once, so I can usually recommend a cure. (There are, however, a few systems that won't run it at all, most commonly due to not liking the old graphics modes.)

I'd like to think I'm in a bit better position to address problems than someone who's never used the program, and I hate to see obscure problems with EZNEC taking up space on public newsgroups. I encourage anyone who has any kind of trouble with any version of EZNEC to contact me directly. I do support the program. And I do gladly honor my unconditional satisfaction guarantee, with no time limit.

The C "float" type is equivalent to the VB Single and Fortran Real variable types, which are single precision (4 bytes) -- I forget what they call the double precision real variable in C. Integers are another matter -- all have the same precision, and the only difference between different sizes is the size of number they can contain. It's hard to believe a compiler can tell when you'll lose precision, since it depends on many factors in the course of the calculation including the order of calculation, as well as the actual variable values. I don't know what kind of "math errors" you got when you tried to use some other language, but it's not because the numerical precision is any less with one language than another. Careless programming in any language can cause errors and loss of accuracy.

I'm not aware of any problem with Basic or VB with regard to variable precision or other issues with variables. I've programmed in HP, DEC, GW, Quick, and other flavors of Basic since the mid '60s, and VB since v. 4. Every language has its strong and weak points, but for many years now mathematical calculation quality has been determined by the hardware, not the language. I suppose the language could have made a difference before the days of the coprocessor. However, my first commercial program, ELNEC, was introduced in early 1990 in coprocessor and non-coprocessor versions, and I never saw a significant difference in results between the two -- and it did some extremely intensive floating point calcualations. So if there was some problem, it must have occured before that.

As a side note, I once fell for the alleged superiority of C with regard to speed compared to Basic, and reprogrammed the calculation portion of ELNEC with Quick C. The result was that the compiler generated about 30% more code than with the Basic PDS I was using, and it ran about 30% slower. Some genuine C gurus where I was working looked over the code and couldn't find anything I'd done which would cause it to run slower than optimum. So there are good and poor compilers in all languages.

This has strayed way off topic, and the OP has contacted me directly, so I'll exit this thread now.

A few years back I put up an OCFD. Feed it with open line. Seemed to
work pretty well and behaved itself running less than about a
100-watts. However, when I increased my power to above 500-watts I was
able to work every electrical and electronic appliance in the house!
The common mode on the transmission can be a killer!

Being the antenna is elevated, I wouldn't expect 8 ft
radials to work worth a hoot, except for 10m.
They need to be resonant. The "same height as
radiator, for usable performance" doesn't really apply
to elevated radials, that need to be resonant. Only
ground mount, will that work ok. Yes, a hat will always
help, but I would just string it with cheap wire, if it's
hidden away in an attic. If on a roof, you could hang
sloping top loading wires, that sloped towards some tie
off point. Or you could use a fancier hat setup....More
$$$ though. :(BTW....In theory, it should be possible to
use loaded radials...Or maybe a 2nd loaded element to
complete the antenna as a psuedo loaded dipole. ?? MK

Then, would the center feed be the best way to go?

For sure. I'd rather center feed, and have to use a
matching device, than use OCF, and not have to use
a matching device. The matching device can be as
simple as a series transformer made from 75 ohm, or
whatever coax. The feed of a 3/2 wave dipole is quite
close to that of a full wave loop. Usually higher than 50
ohms, if clear of the ground. The same series transformer
matching scheme will usually work for either one.
Say if you were on 21 mhz, and the SWR was a bit high.
Say 100 ohms feedpoint impedance, "more common with
antennas high off the ground", you could add 7.6 ft of 75
ohm coax, from the end of the normal 52 ohm feedline,
to the feedpoint of the antenna. That would give you a good
match. Might mess you up on 40m a bit though....I'm not sure
the exact effect it would have on the lower "1/2 wave" frequency.
Maybe not a whole lot...I guess you could switch it in and out
with a relay...BTW....Here, I don't have a very good match on
15 using my 40 dipole, but it's probably cuz I have 160/80/40
on one feedline...I just slap the tuner inline if I want to work 15..
I have used a series transformer on a 3/2 dipole on 20m....It
worked...It was one way I could run a EDZ type antenna, but
easily feed with coax. But...I used .75 wave per side, instead
of the .64 wave per side of the normal EDZ. That tunes out
the reactance, and all you need is the transformer. Sometimes,
you don't even need that as many 40/15 dipoles users know..

1160. Coax Length for G5RV and Center Support for Ladder Line ?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-22 10:17:21 UTC
From: Gary
Message-ID: <42jh61hkuk3vm1gd3rhs3bdm3dl4lkrpvc@4ax.com>
Source record: 78675

I've done a bit of reading on G5RV's and I plan to just use the standard configuration of a 102' dipole center fed with 32' of 450 Ohm ladder line. Then I'm going to attach RG8X to the ladder line and right near the connection construct a current choke of 8 turns of coax about 6" in diameter. And then run the coax to my antenna tuner. some of the sites I've run across mention that the G5RV needs at least 70' of coax to function properly. This seems pretty lossy to me and I don't see the need for the 70' of coax, perhaps someone can enlighten me ? I'd like to keep the run of coax as short as possible.

Also I was digging through my insulators and I can't find one that would offer strain relief for the ladder line and perhaps a connection on top to use a wire or rope to add support to the center of the antenna. I wonder if anyone has a source for one.

Once again, thanks in advance.

HI Gary,

If you have read the excellent Article by Cebik you should take a look at it you can find it at http://www.cebik.com/wire/g5rv.html

The best thing if your using 450 ohm window line would be the ladder grabber think you can get it from the Wireman www.thewireman.com

the 70' of coax helps on 3.5 mhz but i'm with you keep it as short as possible.

Hi Guys,

I'm fairly new to this topic so please go easy!!

I have been put in charge of a RSL broadcast here in the UK. The only thing I'm not sure of is in which direction in relation to a folded dipole antenna does the maximum signal radiate?

I know normal dipole antenna radiate outwards from their ends, but I'm not sure about the folded version.

Please Help.

Many Thanks

Gavin.

Home Depot: 1/'2 PVC or ABS pipe, matching T's, stainless hose clamps.
Clamp one T to the mast, melt or cut a notch in the other T for the
ladderline. Buy threaded pipe and T's or unthreaded and a can of glue.
Put a floor flange on end end instead of a T to bolt to side of
building. Good luck.

Hi Gavin:

Folded dipoles and regular dipoles radiate the same. Your idea of radiating off the ends is wrong. Both types of dipoles radiate their maximum signal at right angles to the plane of the wire. That is if the wire (or tubing) runs north/south the maximum radiation with be east/west. This assumes the dipole is horizontal, if it's vertical then it radiates equally in all horizontal directions. This is for a dipole in free space. Depending on the frequency and the height of the antenna the pattern may change. Such as a dipole for the 3.5-4Mhz ham band mounted 10m up, with radiate most of its signal straight up. I don't know what RSl broadcasting is here in the US so I can't give anymore detailed answers.

If I was going to run open line, I would not go with
an off-center feed. I don't think it buys you much.
On the other hand, off-center feed with coaxial feedline
can buy bandwidth over center feed. Our 80/75 dipole
is off-center fed with a 4:1 voltage balun followed
by a bead balun on the feedline. The SWR is quite low
from 3.5 to at least 3.8 MHz. Solid-state finals and
Alpha 87A finals like it very much. No trouble with
getting into appliances at 1500 watts.

Back in the dark ages, when I was in school, we were "encouraged" to take a numerical analysis course if we were interested in computers. (I was an EE major.) It was not an easy topic, but it made us well aware of the difference between correct results and computational precision. I was recently astonished to find that most computer science students have no concept of this area and even less interest in it.

These current thoughts extend to other areas:

- C is more accurate than Fortran (or Basic, or what whatever)
- Obtaining "stable" numeric results means you get the same answer if you run the program twice
- C produces the fastest programs
- if C is good then C++ is better
- Using all the obscure C operators produces a better program

(Anyone remember the IBM 7030 system? The user could control the rounding direction of the floating point LSB. In this case running a program twice (with different rounding options) really was relevant.)

Gene Fuller, W4SZ wrote:
"As expected from the simple mirror image model there is complete far field cancellation in the phi = 0. theta = 0 direction."

Right. Real and virtual imaqges are equidistant and 180-degrees out of phase perpendicular to the reflector.

The more distant the radiator from the reflector, the smaller its image appears. The phase difference between the radiator and its image varies with the distance between them.

At 1/2-wavelength from the reflector, a round-trip takes 360-degrees and leaves the phase unchanged. However, the reflection inverts the phase. Incident and reflected waves cancel perpendicular to the reflector.

Two antenna elements, or one with its image in a reflectoe, will be directional. An unobtainable isotropic is the reference, so te antenna has gain.

There is no way to mount a J-pole next to a tower and preserve its omni characteristics. The question is which directions would you favor and which would you diminish?

You know the tower may be impenetrable, and the vector sum of incident and reflected signals directly opposite the tower depends on the antenna to tower spacing.

An antenna modeling program should be able io show you your options.

You know thet 1/2-wave spcing cancels in the diretion of the antenna mounted on the tower face. Add or subtract a 1/4-wave to the spacing, and the incident and reflected waves reinforce instead of cancel. As I think Roy said, you pay your money and take your choice.

Best regards, Richard Harrison, KB5WZI

Take a look at plastic electric fence standoffs
available at farm supply places and large home
improvement places. That's what I used. The end
that holds the electric wire fits through the
window in 450 ohm ladder-line.

Balanced center-feeding a balanced antenna will tend to
minimize the common-mode currents but some antennas, like
the Carolina Windom depend upon feedline radiation for
their radiation patterns. What are you trying to
accomplish?

When Osama bin Laden died, he was met at the Pearly Gates by George Washington, who slapped him across the face and yelled, "How dare you try to destroy the nation I helped conceive!"

Patrick Henry approached, punched him in the nose and shouted, "You wanted to end our liberties but you failed."

James Madison followed, kicked him in the groin and said, "This is why I allowed our government to provide for the common defense!"

Thomas Jefferson was next, beat Osama with a long cane and snarled, "It was evil men like you who inspired me to write the Declaration of Independence."

The beatings and thrashings continued as George Mason, James Monroe and 66 other early Americans unleashed their anger on the terrorist leader.

As Osama lay bleeding and in pain, an Angel appeared. Bin Laden wept and said, "This is not what you promised me."

The Angel replied, "I told you there would be 72 Virginians waiting for you in Heaven. What did you think I said?"

I use the black UV-resistant tie wraps for strain relief.
Run the tie wrap through one of the ladder-line windows
and then through the hole in the insulator. With stranded
ladder-line, I have had absolutely no problem with this
method.

Hi Walt, I thought "saved by the bell" was a boxing term.
But someone here reported that they once buried people
with a string attached to a bell on the surface so if
they became conscious after being buried, they could ring
the bell and someone would dig them up. Wonder how many
times that happened?

Cecil, in case you missed my earlier response to yours, because I posted it following one of your previous postings, your comment about how many people in a coma were considered dead before comas were understood is a prime example of dogma fed by ignorance. Jesus' raising Lazarus from the dead comes to mind.

According to EZNEC, here are the 50 ohm SWRs that you will
encounter if your 450 ohm ladder-line has a velocity factor
of 0.9. 3.8HMz, 17:1 7.2MHz, 4.8:1 10.125MHz, 55:1
14.2MHz, 2:1 18.14MHz, 35:1 21.3MHz, 23:1 25.95MHz, 2.5:1
28.4MHz, 60:1. You will definitely need a tuner. One wonders
if you couldn't do better with ladder-line all the way to the
tuner.

Pat,
This is probably worst case, but after installing a new 75 m antenna, I
measured the power picked up by the old one, broadside, and about 30 feet
apart. Got 10 W at the end of the feedline. Unfortunately, I can't remember
if I was running 100W or a KW at the time, but lean towards the 100W.

On the other hand, I have a tribander with a 2m beam 4 feet above it, and a 6m beam 4 feet above the 2. No problems running a KW on HF and 375W on 6. If I were to run a KW on 10m, and turn the 6 m radio to 10 also, that would be a different matter. As it is, there is a Bencher 32 MHz LPF at the output of the HF amp.

OK, so here is the situation.

I have a 10W FM transmitter set to 87.7MHz. I also have a folded Dipole antenna and a 20 meter high mast.

Would it produce and great coverage area with the antenna horizontal or vertical?

Many Thanks

Gavin.

See g5rv's article at http://www.qsl.net/aa3px/g5rv.htm

He said you can use up to 70 feet of coax and not suffer too much
loss; the shorter the better, tho'

He also had other recommendations for feedlines.

Hi Joe,
IMHO it is best to isolate the ground used in the shack from the household ground. This should reduce noise from any mains supplied appliances. You could use a third rod for the antenna no problem.
Good luck,
Rob (M0LET)

It would not surprise me if the "real world" proved this wrong, however:
Vertical should give the greatest circular area coverage (no end
attentuation like a horiz. dipole).
However, most external receiving fm antennas are horizontal in
polarization--most portables have short pullup whips...
If you do go vertical, a 5/8 (at least in theory) drops the lobes of the
radiation pattern and gives you the most usable low angle of radiation
(direct correlation to max distance)...
The vertical is omnidirectional of course--a horz dipole is more
bi-directional...
If any of this is in error--I am sure it will be corrected...

Regards,
John

In the United States, most localities incorporate the National
Electric Code into their own local building codes. It is my
understanding that the NEC requires that each building structure have
precisely one "ground system", and that this requires that all ground
rods be reliably "bonded" together (typically via 6-gauge-or-heavier
wire).

The ground-system bonding is required in order to reduce the degree to
which ground-voltage differentials can occur in the case of an
electrical fault or nearby lighting strike. The bonding reduces the
current that can flow through appliances that are connected to two or
more independent "ground" systems (e.g. a building's main electrical
ground, and a separate ground stake near an antenna).

Putting in a second ground rod near the hamshack can be a good idea,
as it reduces the length of the ground wire from rig to ground rod and
can improve the quality of the RF ground (depends a lot on wire length
and frequency). However, in order to comply with the NEC, this ground
rod must be bonded to the main building ground.

I don't know what the rules are in other countries.

Dave is correct about NEC requires, HOWEVER please check with you local
municipal (or country/parish) building department (or code enforcement) -
there are variations that are more restrictive than NEC in SOME U.S.
localities.

That said, IF you are going to have a tower or large antenna array - RF
grounding needs to be addressed separately from electrical service
grounding. This area also has different requirements in SOME areas (for
example - parts of Florida have the highest lightning hits per year). Glen
Zook, K9STH has given talks and presentations on this subject - this

information can be found here:

For FM Broadcasting this is VERY IMPORTANT. Originally, FM broadcasters used horizontal polarization (usually versions of "halos") for their broadcast antennas. This was fine for fixed or home listeners, who used horizontal TV/FM antennas or folder wire dipoles (included with many stereo receivers) - BUT cars and mobile FM receivers tended to be vertically polarized. In order to address this 2 solutions were used -- one was to add a vertically polarized element to a large "phased array" on the side of the tower. The other was to replace the antenna with one that could produce circular polarization

Here is another circular polarisation article you may find useful.
Simple construction too.

You will obviously need to recalc the dimensions from 144MHz. (Multiply
everything by 144/87.7)

http://home.comcast.net/~ross_anderson/CycloidCollinear.htm

> > thanks

thanks to all those that responded, i should have mentioned that things
with metal such as hose clamps or screws are out as the metal would
bother either the ladder line or nearby antennas prob be small, effect
i guess but still wish to avoid metal

my mast is pvc-- the idea of using pvt T's i think was interesting i
thought of it but didn't kinda workout right, the electric fence
post standoffs were great i've got a few kinds however i can't fine a
way to mount them onto a round pipe the fence standoffs have a hole to
mount via a nail /screw into a flat surface and i didn't want to use a
metal nail

i can't really seem to find anything that would be able to clamp onto a
round pipe stick out about 5in or so, and be nonconducting w/a 'thing'
that could 'hold' ladderline

considering just desiging one and having a plastic company make them for
me custom, if there was a bunch of people /ie a small market for them
it might break even enough to cover the costs i dunno if anyone else
ever has this particular or pecular need??

anyone want any?? i mean would you buy a bag of them for a few dollars?

1197. Good morning or good evening depending upon your location. I want to ask you the most important question of your life. Your joy or sorrow for all eternity depends upon your answer. The question is: Are you saved? It is not a question of how good you are, nor if you are a church member, but are you saved? Are you sure you will go to Heaven when you die? GOOGLE·NEWSGROUP·POST·147

The reason some people don't know for sure
if they are going to Heaven when they die
is because they just don't know.

The good news is that you can know for
sure that you are going to Heaven which is
described in the Holy Bible as a beautiful
place with no death, sorrow, sickness or
pain.

God tells us in the Holy Bible how simple
it is to be saved so that we can live
forever with Him in Heaven.

"For if you confess with your mouth Jesus
is Lord and believe in your heart that God
raised Him from the dead, you
WILL BE SAVED." (Romans 10:9)

Over 2000 years ago God came from Heaven
to earth in the person of Jesus Christ to
shed His blood and die on a cross to pay
our sin debt in full.

Jesus Christ was born in Israel
supernaturally to a virgin Jewish woman
named Mary and lived a sinless life for
thirty-three years.

At the age of thirty-three Jesus was
scourged and had a crown of thorns pressed
onto His head then Jesus was crucified.

Three days after Jesus died on a cross and
was placed in a grave Jesus rose from the
dead as Jesus said would happen before
Jesus died.

If someone tells you that they are going
to die and in three days come back to life

again and it happens then this person must be the real deal.

Jesus Christ is the only person that ever lived a perfect sinless life.

This is why Jesus is able to cover our sins(misdeeds) with His own blood because Jesus is sinless.

The Holy Bible says, "In Him(Jesus) we have redemption through His blood, the forgiveness of sins..." (Ephesians 1:7)

If you would like God to forgive you of your past, present and future sins just ask Jesus Christ to be your Lord and Saviour.

It doesn't matter how old you are or how many bad things that you have done in your life including lying and stealing all the way up to murder.

Just pray the prayer below with your mouth and mean it from your heart and God will hear you and save you.

Dear Jesus Christ, I want to be saved so that I can have a home in Heaven with You when I die. I agree with You that I am a sinner. I believe that You love me and want to save me. I believe that You bled and died on the cross to pay the penalty for my sins and that You rose from the dead. Please forgive my sins and come into my heart and be my Lord and Saviour. Thanks Lord Jesus Christ for forgiving me and saving me through Your merciful grace. Amen.

Welcome to the family of God if you just allowed God to save you. Now you are a real Christian and you can know for sure that you will live in Heaven forever when this life comes to an end.

As a child of God we are to avoid sin(wrongdoing), but if you do sin the Holy Bible says, "My dear children, I write this to you so that you will not sin. But if anybody does sin, we have one who speaks to the Father in our defense Jesus

Christ, the Righteous One."

Those of you that have not yet decided to
place your trust in the Lord Jesus Christ
may never get another chance to do so
because you do not know when you will die.

Jesus said, "I am the way, the truth and
the life: no one can come to the
Father(God)(in Heaven), but by me."
(John 14:6)

This means that if you die without
trusting in Jesus Christ as your Lord and
Saviour you will be forever separated from
the love of God in a place called Hell.

The Holy Bible descibes Hell as a place of
eternal torment, suffering, pain and agony
for all those who have rejected Jesus Christ.

The good news is that you can avoid Hell by
allowing Jesus Christ to save you today.
Only then will you have true peace in your
life knowing that no matter what happens you
are on your way to Heaven.

Praise the Lord!
Servant of the Lord Jesus Christ
Ronald L. Grossi

*Show this to your family and friends so
they can know that they have a choice
where they will spend eternity. Thanks!

Use UV resistant tie wraps.
Feed the tie wrap through the insulator loop over the wire/ladder and
feed back into the insulator. Fasten the tie wrap around the pipe.

Report back.

Rob,

I see that you are in the UK so the concept of a US National
Electric Code does not apply to you so you may regard this as good
engineering practice instead. Joe, The National Electric Code
specifies in section 250 that all grounds must be bonded together at
the safety ground for the service entrance. Your insurance will take
a dim view of non-compliant installations.

Russ

I believe the trend in modern cars is getting away form vertical FM
receiving antennas and going to in-glass horizontal wires for the antennas.

Please, PLEASE, disregard every bit of that RUBBISH about "dissipation" (prevention) of lightning strikes in K9STH's website. There is not one single piece of scientific evidence to any of that bullcrap. The theories of Charge-transfer-systems (CTS), Early Steamer Emissions (ESE) or ANY kind of lightning prevention are total malarkey. The cost of gathering international review and wide publication of DIScrediting these phony's is incredible, but the IEEE has done so over and over again.

There was good advice in this thread (and one bad one, advising isolation of house and radio grounds), until "gb" dragged that old nuttiness about dissipators out of the closet.

Best regards,

Jack Painter

Joe wrote:
"I would like to use this ground rod to ground my Butternut H9V vertical antenna."

USA National Electrical Code requires all site ground connections be connected together. Lacking such interconnections, high transient voltages of vastly differing magnitudes might momentarily appear at different ground rods and at circuit points connected to them. This could lead to injury or damage.

It`s a good idea to provide an antenna ground rod, or rods, directly beneath the the antenna, and to provide a short stout electrical connection between the antenna ground system and the electrical service entry grounding system. The interconnection intends to keep the potential between grounding systems low. Additional lightning protection will often be needed.

Best regards, Richard Harrison, KB5WZI

If I understand correctly the just of these replies, -- I would be better
off if I installed a so-called "stand-alone" ground rod that was several
feet a way from the ground rod that my home was on and use this
"stand-alone" ground rod solely for my shack equipment, and then driving
another ground rod by my Butternut vertical and connecting it to the antenna
ground rod. Am I correct in this? What is confusing to me is what one of
the replies suggested that the rods be bonded or connected together. If that
is a correct thing to do I don't see what the difference would be to using a
single ground rod. After-all a ground rod is a ground rod.
Thanks again for all your help.

" but the IEEE has done so over and over again".

As a member of IEEE, ... my esteemed association strongly supported BPL ..
which I consider a rubbish, politically motivated usage of network
technology.
Their creditability is suspect moving forward.

As for NEC -- Chicago area standards which are stricter - and will not
permit some lower requirements under the NEC.

As for what is important at the end of the day - I have found that unless
the insurer for the property and equipment
agrees with the installation (and design) -- they won't pay for damage - no
matter what was followed !

Although single point grounding should be used (as Jack points out) - over the past 30 years I have seen so many "in the field" violations of that principal (telephone, power, cable, broadcasting companies) -- and I am not the policeman for these installations or their engineering arguments - why they were installed that way.

Thanks Cecil, I had that idea in the back of my head but didn't know
how practical it was. I've got large number of black tie wraps
already. I don't know if they're UV resistant or not but I'll give it
a try.

Well I've got two MFJ tuners (one for use while the other's in for
repairs ;-)) . The 949E is in for repairs, I've had it for about a
year or so and (I think) the diodes popped on the SWR/Wattmeter
circuit. The other tuner is the MFJ -993 Auto Tuner. The auto tuner
probably won't tune anything over 30:1 and I doubt the 949E would
either. But I'm primarily interested in 80/40/20 meters where the
tuners will handle the SWR. I could use the ladder line to the tuner's
wire input but that would require it to go through the 4:1 balun and
that would make it too low for the frequencies I'm interested in so
I'll probably just stick with a real short run of coax and use the
regular 52 ohm coax input.

Thanks for the information.

Joe,

I didn't just suggest that the grounds be bonded (connected electrically), the NEC requires it. Placing a ground near your antenna base and near your shack will provide a path from your equipment to the ground that is less than a quarter-wave at 30 mHz. This will help keep the ground wire from radiating. If you do not comply with the NEC sec. 250 requirement, your insurance carrier has a case for not paying your claim. Multiple ground rods lower the impedence to earth in case of a lightning strike. Lightning is largely RF and will "prefer" a low impedence to earth. Bond the grounds together with #6 or larger wire. Don't take my word for it, ask your insurace company. I am a former Telco employee and grounding there is a religion, and not a minor one. See the BSPs ("Bell System Practices", now "Best Suggested Practices") and the web site of the Erico corporation. A. J. Surtees is one of THE authorities on grounding.

"Joe" <joe@telnet.com> wrote
> If I understand correctly the just of these replies, --

I'm afraid you still didn't get the gist, Joe...

We could start over:

1.You want to set up shop in a basement.
2. You will have a Butternut vertical antenna nearby.
3. You want to know what should be grounded, and specifically where.
4. You asked about a bus-bar ground panel behind your radios.

We don't know where your main house AC power panel is, or what kind of ground system it uses (could be the home's cold water supply pipe, a buried copper plate, or buried copper ground rod). This will be important later, and as others said, it is generally accepted practice and code in most countries to require that all systems use either one single grounding point, or bond any supplemental ground points to it. You should do at least some basic research on your own about grounding and bonding, if this is not abundantly clear to you.

Your vertical may or may not require the use of RF radials, counterpoise, etc. Consult the manufacturers recommendations there, and follow them exactly. If you do use a radial system or buried copper wires, some common point of that system must bond to both the home's AC service ground point *and* the radio equipment's ground rod, if separate ones are used. What you do with your antenna and radio ground rods are entirely up to you. Electrical codes do not cover bonding RF grounds and an separate radio ground rod to each other. But a hundred years of sound lightning protection science *does* require that you always bond ALL ground systems together, NEVER leaving them isolated from each other.

It gets very expensive to provide high voltage isolation transformers capable of safely isolating neutrals and ground systems, and while possible this is never a goal of the hobbyist. Bonding everything should be your goal in maintaining the basic forms of lightning protection.

Next, you can consider AC surge protection at both the AC entrance and radio equipment. This is the protection from surge voltages that nearby lightning imposes on either the incoming power lines, or magnetically onto the house wiring.

Included in the category of surge protection are Surge Protection Devices (most still call these lightning arrestors) that install in-line on your coaxial or open-wire feedlines. These SPD's limit the amount of damaging voltage presented to your radio's receiver circuitry.

Coax shield grounding (braid of the coax connected to ground rods at several points as required) is what keeps damaging voltages off the exterior of the radios, including your fingers, and limits back-flow of destructive current out the back of the radios and into your homes AC wiring. The critical bonding of radio and shield-grounding rods to the homes AC entrance ground is of major importance here also. If you do not provide a very low impedance path around your equipment, surge voltages can force one through your equipment.

A copper bus-bar or other wide low-impedance "collector" of single point grounding and bond points of all radios can be centered behind your equipment as you asked. But avoid daisy chaining radios in a series to bond them. As inconvenient and hard to conceal as it may be, individual bonding connections from each radio, straight to the single point ground (for the radio shack) is important. This not only provides the only approved bonding method for lightning protection, but limits ground-loop noise between equipments.

Hope this helps tie some of the other good posters comments together.

It's a long read, but I tried to cover most of the points of a total lightning protection system in this website. It might clear up how important the bonding is, I hope!

Vile 5 wrote:
"I would like to build a passive antenna for my cell phojne that has no port. I know it goes into the 1100 MHZ range if that helps."

J.D. Kraus invented an antenna in 1938 that may help. He called it a corner reflector.

The ARRL "Antenna Book" has tables and construction details, but you might get by by making a cardboard corner papered on its inside with aluminum foil. to make a reflector for your cell phone. You might make it twice as wide as it needs to be so that you can make a 90-degree bend in its middle. both reflecting panels (either side of the fold) may then be one or two feet on a side.

You might wrap the reflector around the phone and your head while you aim the interior angle in the direction of the repeater which serves you best. You may get around 10 dB gain which is enough to make a difference but not solve every problem. Don`t bother trying to patent the corner reflector. Kraus and RCA did that back in 1939 or 1940, I believe.

I would agree that some manufacturers - Ford and BMW to name but two -
have in the last decade or two used heated rear window antennas, but
if you look closely you will find that they have vertical components
as well - the side connector strips and often a 'joining' strip down
the centre as well. If they did not, by definition, the horzontal
elements would make the aerial quite directional - as the
manufacturers found out the first time round in the '70's.

In Europe and certainly the UK (a) many transmissions are not circular
but of mixed polarisation (i.e. crossed diagonal) to give a vertical
component for car and portable use and a horizontal component for the
many still horizontal roof aerials fitted over here from the days when
all FM was horizontal, and (b) many cars over here have either a
conventional angled whip on the front of the roof (as with Citroen and
Peugeot) or the ubiquitous 'bee-sting' amplified whip on the rear of
the roof.

One does notice how many American import cars over here still have
wing mounted vertical aerials - perhaps that is why there is so much
difference between them and us?

Hello!

The AEA CIA/VIA antenna anylyzer gives an extremely low output signal and I have heard that it is possible to slightly increase this output by reducing the value of a resistor. I do not have the schematic so I wondered if anyone else has done this modification and if so would help me to do it.

Best wishes

Andrew G3WZZ/OZ5E

Gavin wrote:
"I know normal dipole antenna radiate outwards from their ends, but I`m bot sure about the folded version."

The propagation pattern from a dipole forms a toroid centered on the middle of the dipole wire. Radiatiation is perpendicular too the center of the wire. There are nulls at the ends of the wire.

Adding a wire or wires between enda of the simple dipole does nothong to change its radiation resistance, antenna efficiency, directional pattern, or directive gain. Drivepoint impedance increases with added wires as total antenna current is divided among them. If two equal wires are used in the folded dipole, its drivepoint impedance is four times the impedance of the single wire dipole. If there are three wires, the impedance is multiplied by nine. Impedance varies by the square of the number of same sized wires in the folded dipole.

Best regards, Richard Harrison, KB5WZI

I agree that you should at the very least take K9STH's advice regarding lightning with a grain of salt. There is some good advice about grounding, but there is also some bad advice, and most of his theories about lightning have been replaced in the last 20 years among the scientific community.

Also, the way I see it, we ground our gear for low noise and good radiated signals. NEC grounds things for safety and lightning protection. What constitutes a "good" ground system may differ according to which viewpoint you adopt.

A metal nail is resonant at such a high frequency that it
wouldn't bother anything. How about brass screws?

> i can't really seem to find anything that would be able to clamp onto a
> round pipe stick out about 5in or so, and be nonconducting w/a 'thing'
> that could 'hold' ladderline

You should be able to attach the electric fence standoffs
to the pole using black UV-resistant tie wraps. You may
have to drill a hole at the proper place on the standoffs.

Why would anyone put their faith in a religion that includes
burning in hell forever? I have complete faith in one of the
Eastern religions where God keeps recycling souls - sending
me back over and over until I finally get it right.

Quite ironic given that Jews, Christians, and Moslems
all worship exactly the same God-the-Father and have
essentially the same early writings in their holy books.
It reminds me of sibling rivalry. Has anybody asked
Yahweh/Jehovah/Allah what He thinks about all this
ridiculous in-fighting among His children?

Anyone else see the irony in a "Death to Unbelievers"
concept applied to individuals who all believe in the
same identical God-the-Father=Yahweh/Jehovah/Allah?
(When Jesus prayed to God-the-Father in Aramaic, he
no doubt prayed to Allah.)

Gain wrote:
"I have a 10W FM transmitter set to 87.7 MHz. I also have a folded dipole antenna and a 20 meter high mast."

Range is determined by line of sight.

Your antenna is about 66 feet high. Over smooth earth, your grazing point, in miles, is the square root of twice the antenna height in feet, or the sq, rt. of 132 = 11 miles. If your receiving antenna happened to be at the same elevation and could share a grazing point, the total distance you could reach is 22 miles.

Antenna polarization has little effect on range unless you can cross-polarize with an interfering signal which is unlikely. Broadcast stations in the U.S.A. use both polarizations as many listeners are in vehicles which have better luck with vertically polarized signals. The same conditions prevail everywhere.

Have luck and fun. Try to stay out of jail.

Best regards, Richard Harrison, KB5WZI

Gavin wrote:
"What eould this achieve?"

I suppose this relates to radiation from the dipole`s ends.

There`s not much from the ends of a dipole in free-space. Radiation from a dipole in free-space is patterned as a doughnut symmetrically placed around the axis at the dipole`s center.

Kraus in his 1950 edition of "Antennas" on page 133 wrote:
"The pattern is independent of phi, so that the space pattern is doughnut-shaped, being a figure of revolution---."

Down the same page:
"However, the near-field pattern for Er, is proportional to cos theta as indicated by Fig. 5-6b." (shows fields about the ends of the dipole)
These are mostly reactive fields which don`t radiate.

Best regards, Richard Harrison, KB5WZI

MAKE FAST MONEY WITH PAYPAL - ONLY NEED $5

Subject: Make Money Fast Using Paypal Author: Joe Date: 11/20/2004 7:29:50 PM MAKE UNLIMITED MONEY USING PAYPAL!!! You only need $3.00. Can you really make money so easily? YES... it is logical how you can earn money through paypal. I found articles with OPRAH WINFREY and an article published in the Wall Street Journal on 6/16/2001 that explains

how it works. As a member of PayPal, I had already experienced their efficiency and excellent standing. PayPal is the simplest method of making and receiving payments online anyone has ever seen! Anyone with an email address can join, for FREE! You can complete this whole process in less than one hour. Everything is done on the Internet by E-mail. It is NOT considered SPAM, so it's perfectly legal! Anyway, it said that you send money though paypal to each of the emails stated in the article. You then place your own email address in the bottom of the

list at #6, and post the article in at least 200 newsgroups. (There are

thousands it really isn't hard..try it this is where people usually stop and miss out) No catch, that was it. It follows the same regulations as the mailed chain letters, which according to the U.S. Post Office (1-800- 725- 2161) is indeed legal! Then I invested the measly $5.00. Well GUESS WHAT!!?. Within 7 days, I started getting money in my PayPal account! I was shocked! I figured it would end soon,

but the money just kept coming in. In my first week, I made about $20.00. By the end second week I had made a total over $1,200.00! In the third week I had over $10,000.00 and it's still growing. This is now my fourth week and I have made a total of just over $36,000.00 and it's still coming in rapidly. Its Certainly worth $5.00., I have spent more than that on the lottery!! : Let me tell you how this works and most importantly, why it works? REQUIREMENTS: You must have a verified PayPal account. If you do not have an account you can go to www.paypal.com and follow the instructions to set up a free account. In

order to place the initial $6 into your account, you will have to verify your bank account with PayPal (which may take a few days). Or if

you want to start right away, use your credit or debit card to make the

$6 deposit to Paypal. Paypal guarantees your security when using personal information. They do not release your information to third parties. Very, very, very, secure! Paypal is 100% secure and is used my

millions of people world wide. STEP 1: Send, though PayPal, $1.00 to each email on the below list. Make the subject of the payment "Email

List" and in the comments, write "PLEASE PUT ME ON YOUR EMAIL LIST." What you are doing is creating a service by this and best of all you are not giving your address to anyone you do not know. THIS IS ABSOLUTELY LEGAL! The E-mail list: #1)canderson1...@comcast.net

#2)stephse...@yahoo.com #3) paperclip...@hotmail.com #4) ingomanba...@yahoo.com #5)
carney1...@yahoo.com. #6) Lovegirlkatie@aol.com STEP 2: Now take the #1 email off the list that
you see above, move the other addresses up (6 becomes 5, 5 becomes 4, etc?.) and add YOUR email address (the one used on the paypal account) as number 6 on the list. STEP 3: Change anything you need to, but try to keep this article as close to original as possible. Now, post your amended article to at least 200 newsgroups, message board. (I think there are close to 32,000 groups) All you need is 200, but remember, the more you post, the more money you make - as well as everyone else on the list! ---- DIRECTIONS----HOW TO POST TO NEWSGROUPS, MESSAGE BOARD---------- Step 1) You do not need to re- type this entire letter to do your own posting. Simply put your cursor at the beginning of this

letter and drag your : Cursor to the bottom of this document, and select 'copy' from the edit menu. This will copy the entire letter into

the computer memory. Step 2) Open a blank 'notepad' file and place your

cursor at the top of the blank page. From the 'edit' menu select 'paste'. This will paste a copy of the letter into notepad so that you can add your name to the list. Step 3) save your new notepad file as a .txt file. If you want to do your postings in different sittings, you'll always have this file to go back to. : Step 4) Use Netscape or Internet explorer and try searching for various newsgroups (on-line forums, message boards, chat sites, discussions.) Just example you log on any search engine like yahoo.com, google.com, altavista.com, excite.com then you search with this subject ? millionaire message board? or ? money making message board? or ? employment message board? or ? money making discussions? or ? money making forum? or ?business message board? etc. You will find thousand & thousand message board. Click one by one then you will find the option post a new message. : Step 5) Visit these message boards and post this article as a new message by highlighting the text of this letter and selecting paste from the edit menu. Fill in the Subject, this will be the header that everyone sees as they scroll through the list of postings in a particular group, click the post message button. You're done with your first one! Be Honest and it will truely work for you:
Congrats!
REMEMBER, THE MORE NEWGROUPS YOU POST IN, THE MORE MONEY YOU WILL MAKE!! BUT YOU HAVE TO POST A MINIMUM OF 200!That is it You will begin receiving money in your account from around the world within days! JUST

MAKE SURE ALL THE ADDRESSES ARE CORRECT. Now the WHY part out of 200 postings: Say I receive only 5 replies (a very low example). So then I made $5.00 with my name at #6 on the letter. Each of the 5 persons who

just sent me $5.00 make the MINIMUM 200 postings, each with my name at # 5 and only 5 persons respond to each of the original 5, this is an additional $25.00 for me. Now those 24 each make 200 minimum posts with

my name at #4 and only 5 replies each. This brings in an additional $125.00. Those 125 persons turn around and post the MINIMUM 200 with my

name at #3 and receive 5 replies each, I will make an additional $625.00. Ok, now here is the FUN part, each of those 625 people post a MINIMUM of 200 letters with my name at #2 and they receive 5 replies each. That just made me $3,125.00!!! Those 3125 persons will all deliver this message to 200 newsgroups with my name at #1 and if still 5 persons per 200 react, I will receive an additional $15,625.00!! With

an investment of only $5.00!! A - M - A - Z - I - N - G - !! When your name is no longer on the list, you just take the latest posting in the newsgroups, and send out another $6.00 to Email Addresses using Paypal on the list, putting your name at number 6 again. And start posting again. The thing to remember is that thousands of people all over the world are joining the Internet and reading these articles everyday. JUST LIKE YOU ARE NOW!! So, can you afford $5.00 to see if it really works?? I think so! People have said, "what if the plan is played out and no one sends you the money? So what! What are the chances of that happening when there are tons of new honest users and new honest people

who are joining the internet & newsgroups everyday and are willing to give it a try?? Anyway, it is only $5.00 for a chance at thousands. Estimates are at 20,000 to 50,000 new users, every day, with thousands of those joining the actual Internet. Remember, play FAIRLY and HONESTLY and this will really work. There's no use trying to cheat for only $5.00 *** Pls. use only opt-in resources for this material it will

work for you and it works much faster without soliciting or spamming and higher responses*** !!! With warm wishes, bless you and your loved ones.

Bob, it gets even worse when total lightning protection systems are involved.

This book below (Grounding v. Bonding) is an excellent fundamental approach to the interrelationship between the two. Add to it the $35 NFPA-780 (Oct 2004 is current edition) Standard for Installation of Lightning Protection Systems, and you will be a long way toward understanding how to best protect equipment in your individual circumstances.

I don't understand the "sloping top loading wires, that sloped towards
some tie point". You have a picture of something like this?.......

Just visualize a upside down ground plane, with the radials on top,
instead of the bottom. That's about what it would look like. They could
slope a bit, and I don't think it would hurt too much. I think it will
be more
effective as a hat, if you can connect the ends of the wires to make a
outer
loop. But you don't have to do that. If you had it in the attic, and
the roof/
rafters were all wood, with no metal, you could have the tip of the
antenna
near the roof/rafters, and just run the hat wires along the rafters.
But ya still have to worry about those ground radials....:(...
It might be easier to make some kind of attic dipole, or loaded dipole,

using two elements back to back. That type antenna requires no
radials.
I have two attic antennas myself...One is a 2 m ground plane, hung from
the rafters, and the other is a 40m dipole, that is fed with 300 ohm
line
to my tuner. It will work 40-10 ok...It's kinda of a backup I can use
if the lightning is so bad in the area, that I don't want my regular
outside
antennas connected. I even unhook it, if it gets real close.

SNIP--------------------

Ok, I'm going to try this as soon as I can get my son over to do the leg work before the attic temperatures exceed 100 deg. or more. I am not allowed to climb anymore and I do miss messing around with antennas and sunshine and gulf breezes. Today would be perfect. I shall report back my findings.

hi

While this might sound simple for most, i kinda have a a little trouble visulizing the best 'physical' layout of some stuff...

couldn't find any guides to use as a sample thought someone here might have some picutres or .ppt or visio layouts...

I am trying to set up my new hamshack w/o a rats nest of wires for once

i have a rig on my desk and a shelf about 2ft over it with my tuners, pwr supply another rig under it i've mounted a small light(ac) 2 alphadelta coax swithcs and 2 ice lightnng protectors and a inline balun

my space is limited, and seems it'd be difficult to have some wires that didnt cross or go parallel for a bit or at some point, again perhaps not if i could 'see' things better

using my rf cables as the starting point i've attached a nice cabel tray for them it's covered looks nice not rf proof

i stopped cauze i wonder if my dc cables cross over that or run along it will that be detremental to the coax??

how about he ac if the ac cables run near either my coax or dc is that bad

the two ways i might do it would be either at a cross 'X" ie right angle the other might be parrallel spaced a few inches apart

aside from the above' anybody have any nice pictures of a ham shack installs showing nicely mounted wires all dressed , tied down and run right??

thanks

1243. Heil Clear Speech Speaker

The Heil Clear Speech Speaker arrived today and I got busy installing it. I gave it a quick operational check then took it apart and photographed it inside and out. I also scanned the Owner's Manual and created a pdf file from it. I did have to add an Amidon core to the power lead and the signal input lead since with 1KW I had RFI feedback. The cores resolved it 100%.

I am so very pleased and yes after the 746 Pro dopes all it can to reduce noise the Heil Clear Speech Speaker can and does further reduce the audio noise dramatically. I purposely tuned several weak and noisy stations on HF and VHF and the dsp speaker did make an unworkable signal literally arm chair copy..no kidding. Years ago I had the AmCom Clear Speech Base box on my TS450 and it gave similar results. These things really do work.

See photos and download manual here....

Yes, got to the library and copy sections 250 and 800 of the National
Electric Code (NEC). It is quite clear and if you have passed element
two you should be able to understand the language.

I'll repeat myself because it bears repeating. All grounds are to be
bonded together with at least #6 wire and mechanical connections (no
soldering).

Bob Miller wrote:
"Is there a good layman`s book on grounding amateur gear?"

The ARRL Handbook for starters, My newest is the 1987 edition. It has several pages of good suggestions on "The National Electrical Code", protective devices, and lightning protection. They suggest books and pamphlets to request for planning your installation.

There is no big disparity between lightning protection and electrical noise abatement. The techniques are almost the same. I`ve checked lightning prepared status by checking noise rejection capability. Lightning is an enormous noise.

Want complete protection? Seal your protected treasure inside a seamless box constructed of highly-conductive sturdy material. No wires enter and no wires leave. No noise, no lightning, and no damage to the contents either.
Now, bring wires through the box but use a series impedance in each (a choke), and use a shunt admittance (a capacitor) between each wire and the box. Better yet, confine the area where wires enter and leave the box to a small space or window so that all the ground connections can be made in the same spot. Again, no noise, no lightning, and no damage to contents inside the box.

It works. I`ve done it.

Best regards, Richard Harrison, KB5WZI

"Effective":

A. Can hit the local 2m repeater.
B. Can work all states on 2m.
C. Can work moonbounce.
D. Can work weak stations via moonbounce.
E. Can make HF contacts with my kW rig.
F. Can make HF contacts with my 100 watt rig.
G. Can make HF contacts with my 5 watt rig.
H. Can make HF contacts with my 100 mW rig.
I. Can work some DX on HF.
J. Can work DX on all HF bands.
K. Can break pileups on rare DX stations.
L. Can create pileups of rare DX stations every time I transmit.
M. Can create pileups of rare DX stations every time I transmit with my
100 mW rig.
N. Can win major DX contests with ease.
O. Can have the loudest signal on 160 meters.
. . . .

Then there's "optimum". . .

You are a fucking dickhead.

1256. My homebrew 432 Quagi results

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-24 03:14:27 UTC
From: Scott <acepilot@bloomer.net>
Message-ID: <vpWdne5Tp4CckvbfRVn-2w@bright.net>
Source record: 78621

Might be interesting to someone out there....

I built a copy of the 432 Quagi (8 elements) that appeared in the 1988 ARRL Antenna Book. It has a "claimed" gain of 13 dBi (which, if I remember right, is 10.8 dBd).

I didn't lament over getting all the elements within 1/128" of an inch ;) and it came out OK. The only place I needed to deviate fairly significantly is that I needed to move the first director about 3" forward of the original design to get a better match. I have no idea what this will do to the radiation pattern. As designed, mine had a best SWR of 2:1, causing the solid state final in the Yaesu 857 to start shutting down such that I was getting about 6 or 7 Watts out instead of 20. Moving the first director forward as noted got the SWR to 1.2:1. Much as I would expect since a quad element at resonance is about 60 Ohms I believe. Anyhow...

Measured it on the antenna range today at our VHF group's (http://www.nlrs.org) annual get-together. My antenna came in with a 9.6 dBd gain. I can live with that! It was only 0.3 dB below the reference antenna, an 11 element Yagi. Seems to have a very sharp pattern!

Anybody have experience with this type antenna? I was impressed enough to think about giving the 222 version a try...

Good to see you today, Scott. Finally a "nice day" for Aurora - 45 degrees, sunny, and 15 mph north winds. Much nicer than the last 2 years, eh?

I have many 432 designs that will work better than a quagi on the same boomlength. The quagi as you made it has a significant amount of feedline radiation, and the gain could be a lot better.

Drop me a note, and I can give you plans, including the T match. If you dont have delron element insulators available, there are cheap substitutes you can make from plastic wall anchors.

And 222 yagis are available also. I have K1FO yagis scaled to all bands that are appropriate.

Look for an identical item sold by a different vendor. Motorola has often sold antennas manufactured by a maker supplying identical items with various brand names. Mahk Products used to make many Motorola Antennas, all duly Motorola part numbered and listed in the Motorola catalog. With any other part number it works just as well if it is identical.

I should have advised you to clamp the voltage on each wire entering your lightning protected enclosure to a safe maximum voltage for that wire. The ARRL Handbook mentions several appropriate devices, fast acting and proper breakdown voltage range to protect your equipment. These protectors are used in addition to the filtering which is used for low-level noise elimination.

All kidding aside... a digital speech processing app is an excellent idea. However, you can get them for free (download off the internet!) Then, by using either the line in (preferred) or mic input on the sound card of your computer, and your computer speakers or sound card output--you can process that audio to unfathomable depths!

Regards,
John

Scott,
A few years back I scaled that 432 design to 440 and while I didn't
measure the gain, I found that the match wasn't bad (about 1.3:1) on
the first try - so I left it. That could have to do with the fact
that all I really scaled were the element lengths and I left the
spacing as-is. As to performance? Grand! The company radio club had
a "far and away" contest - who could hit the repeater from the
farthest distance; my straight line distance from the repeater was 106
miles (gotta love GPS) and using 5 watts I had workable voice contact.

As Tom suggests in his post, there are better designs - however, I
think that on a "dollar per dB" basis and ease of construction the
quagi is hard to beat.

1270. Accuracy of Antenna Testing Ranges

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-24 05:44:34 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <d4fbo2$g5a$2@nwrdmz02.dmz.ncs.ea.ibs-infra.bt.com>
Source record: 78535

All electrical calibration and testing laboratories issue tables of claimed accuracies of measurements. Measurement uncertainties stated on calibration certificates are legally binding. All stated measurement results must be traceable to International Standards or a laboratory or testing station loses its status.

Consequently there is no incentive for a laboratory to overstate its capabilities in its sales literature. Indeed, it is dangerous, illegal even!

Naturally, laboratories can differ widely, one from another.

It would be interesting to compare laboratory uncertainties with performance figures claimed by antenna manufacturers. Or anyone else.

Does anyone have typical examples of measurement uncertainties claimed by antenna testing stations? Answers in decibels please.

A reply from a testing station, at HF or VHF, would be specially appreciated.

Reg, G4FGQ

Well, I won't claim that it's layman-level or that it's small, but I
do keep a copy of the U.S. Government's military handbook on grounding
on my server's website:

http://www.radagast.org/~dplatt/hamradio/mil-hdbk-419a-grounding.pdf

Lots of good information there about ground rods, bonding, making
solid connections between elements of the ground system, etc.

There is also plenty of information on the ARRL website. The ARRL Technical Information Service contains good information on a huge range of technical questions:
http://www.arrl.org/tis/

For an overview on grounding, and how the separate requirements for mains safety, lightning and RF grounding join together, start with:
http://www.arrl.org/tis/info/grounding.html

Searching the whole ARRL site for "grounding" brings up other references as well.

By the way, almost all homes in the UK are categorically exempt from specific lightning protection requirements in the Wiring Regulations... but that also means we are not very lightning-conscious, and UK radio amateurs tend to be very careless about bonding of mains earths and RF earths. This is a case where we'd do much better to follow US earthing principles, if we possibly can.

Good matching on a quagi depends on getting the loop length just
right... which in turn depends on using exactly the same insulated wire
as the original author. This becomes increasingly critical with
frequency, so at 432MHz .

Moving the first director, or bending the ends backward or forward in a
symmetrical V-shape, is a very common way of optimizing the impedance
matching. With most yagis it has very little effect on the gain and
forward lobe, though it may affect the F/B ratio.

>Measured it on the antenna range today at our VHF group's
>(http://www.nlrs.org) annual get-together. My antenna came in with a
>9.6 dBd gain. I can live with that! It was only 0.3 dB below the

Range measurements are the only way to find out if your antenna is
really delivering the claimed performance, and those seem like
reasonable numerical results.

>Seems to have a very sharp pattern!
>
Welcome to the world of long yagis! If you think an 8-element is
"sharp", wait till you've built something really ambitious.

>Anybody have experience with this type antenna? I was impressed enough
>to think about giving the 222 version a try...

Quagis are OK, and easy to build, but nothing special compared to other types of long yagi.

There is no simple reply, Reg, but you're very welcome to come down and read three box-files full of references on this subject.

It all depends what you're trying to measure: simple forward gain or the complete directional radiation pattern; absolute or relative gain; and whether the antenna is a beam or something less directional.

The kind of measurement that is subject to the least errors is a comparison of forward gain between two or more directional antennas that are very similar. The more similar the antennas under test (AUTs) are, the better the errors in each individual measurement will match and cancel out. The more directional the AUT is, the less its gain measurement will be affected by unwanted reflections.

The largest source of error in this case is probably in the uniformity of field strength and phase across the test space where you will position the AUT. There is no single answer in dB for this: you would have to estimate the error-bars by modeling on a case-by-case basis.

Amateur measurements, such as those made by VHF Groups in the USA, typically use a ground reflection range technique that creates a test volume at a height of about 6-10ft above ground, to make it easily accessible by standing on a picnic table and waving the antenna about by hand, but these practical needs will also increase the errors compared

with a professional range with remote-controlled positioning and more time to do it properly.

However, within their limitations, careful amateur measurements can make valid better/worse comparisons between very similar antennas. Reproducibility of gain measurements on the same yagi is within a few tenths of a dB... and the more similar your AUTs are, the closer you can approach this limit when comparing different antennas.

Absolute gain measurement is an additional can of worms. The most common amateur mistake is to attempt to measure gain in dBd by comparing a long yagi against a reference dipole. BIG MISTAKE! A dipole is so non-directional, it makes the so-called "reference" measurement very vulnerable to stray reflections that a sharper beam just doesn't see, so any so-called "standard dipole" is in fact totally worthless.

Or even worse than worthless, the "results" can be anything you want, wish or dream of. Amateur antenna literature is full of such examples, all fueled by over-active imagination.

The solution is to use a reference antenna that is as directional as the AUTs, and to measure or compute its gain by some other means. For example, there is an IEEE standard gain reference antenna that has been designed to be both directional and reproducible (in the sense that its gain is quite tolerant of construction errors) and the gain of that antenna has been very carefully measured under the best possible lab conditions. For microwaves, the usual reference is a standard horn antenna whose gain can be both measured and computed.

What amateur groups like Scott's tend to do is to keep a "gold standard" reference yagi that is used for all their own measurement meets - and above all, to put much more faith in the *relative* gain comparisons than in the claimed absolute gains.

For HF antennas, the required physical size of the test range scales up with the wavelength, and all the problems about range reflections and non-directional of AUTs become impossible for professionals and amateurs alike. That means even professionals are thrown back to computer modeling... which amateurs can do equally well.

I built a 220 version out of a piece of the gray electrical conduit (suspose
to be more UV resistant than the PVC) , used stainless steel welding rods
for the director elements. It worked out very well for me. I compaired it
to the 11 element CC dummy load antenna and it was much beter. I then built
2 of the 440 versions and never did get the swr to where I wanted it. Think
I gave up on them and went to a K1FO type 22 element yagi.

John,
As you can see from the posts there is no 'one' answer
for that question. Just depends on exactly what you are
interested in doing.
The 'average' antenna farm is squeezed into an average
city lot, with variable compromises. The 'optimum' antenna
farm fits in an area something the size of Kansas (with over-
lap in the surrounding states). Again, with variable
compromises.
The 'typical' answer is whatever area you happen to have,
with variable compromises...
'Doc

I looked but could not find the dimensions for the ClearSpeech. I am
very tight for space and have the speaker on my mobile wish list

The pictures aren't any help as there is no reference point

ANy help would be appreciated

Thanks

Steve KF2TI

Reg,
Probably because the 'victims' don't stay happy? Not
to mention that it's illegal in some places, and the fine
doesn't make people too happy either (not that I've ever
heard of anyone being prosecuted). But, if any of that
makes someone happy, then be my guest!
'Doc

My Am-Comm is 5.5"w x 4.5"h x 2.5"deep. I have it
mounted close to my ear velcro'ed to the rear
window in my GMC pickup.

i would bet my 'average' is closer. once you count up all the licensees who have nothing up, add in all the ones who just have a rubber duck on their ht, and then add in the ones who have at most a mobile station, i'll bet you end up closer to the roof of a car as average than a city lot.

Interesting topic Reg. I have always been concerned with uncertainties involved in antenna measurements. ATR antennas do not always provide the source for calibration, but assume it could be ANSI/IEEE Std 149-1979. ETS-Lingren quotes, for their conical log spiral, model 3102 antenna factor uncertainty as SAE, ARP 958 1M (With which I am not familiar). The antenna factor uncertainty is specified as +/- 0.8dB from 1 - 10 GHz. More data, including other conical log spirals, biconicals etc. is available on ETS-Lingren's web site at www.ets-lingren.com if anybody is interested.

One company I worked for was making measurements in a 3 meter shielded ATR. Their distance measurements from the source were measured from the support pole of a conical log spiral, when it should have been measured from the tip. With the 3102 antenna this introduced a 3 dB error. Radiated spurious limits quoted in V/m were also assumed to be peak, but not specified. Some research indicated that these limits are in fact RMS -- another 3dB error! When used for linear field measurements the conical log spiral gain is 3 dB below that for circular polarization. Conical log spirals are calibrated with a circularly polarized signals.

Agilents 11940A has an antenna factor uncertainty of +/- 2dB from 30 MHz to 1 GHz, and is calibrated in the far field, for near field measurements. ETS-Lingren's antennas are all calibrated at 1m irrespective of frequency.

When questioned about accuracies of measurements people usually say "This is the way we have always done it". I have very little experience with HF outdoor measurements, but have heard of sites using high wooden towers to minimize ground reflection effects. A helicopter is required to plot the field strength. Very few EMC antenna manufacturers seem concerned with low frequency far-field measurements. Siemens was about the only company I could find for such measurements.

Regards,

Frank (VE6CB)

1293. Another question regarding single point grounding

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-24 15:32:44 UTC
From: Larry Rappaport <rapp@lmr.com>
Message-ID: <scen611fpi74b6s51rp3tagggc1l6sa5pm@4ax.com>
Source record: 78557

I use a single point grounding system. There is a ground rod driven at the service entrance to which electrical, telephone, and one of two satellite systems are connected. I have run #2 copper from that location to a total of 14 other ground rods each one 5/8" x 8', driven completely in the earth and spaced at least 10' from each other. My 70' guyed tower is about 80' from this location and connected to the grounding system. Each guy wire is also grounded. The aluminum plate where all antennae enter the building on the second floor is connected to this grounding system with #4 copper (to be replaced this summer with 4" flat copper ribbon). Inside the building, there is a bus bar which is connected to the flat aluminum plate where the antennae enter. All the feedthroughs use gas plug protectors. All coaxial feedlines are formed into a coil before being connected to the pass-through plate.

My question: Some radio equipment are also grounded by three prong plugs. Doesn't that constitute a ground loop? I've never gotten a satisfactory answer to this question.

Thanks,
--

Source record: 78558

Dear Bill:
I too am appalled at the abandonment of a solid numerical analysis
course in engineering education. Consider the common problem of solving a
set of linear, independent algebraic equations. Students have to be shown
that Cramer's rule will not work when using the (inevitable) finite
resolution of a computer or calculator. Of course, some of the time
Cramer's rule does work so it is important to teach students why it does not
work in general.
This is relevant to antennas where we routinely need to solve large sets
of equations. When using a computer to perform calculations, one needs to
think differently about methods than in the day when one needed to use large
sheets of paper and a pen.
If one is to use numbers, one needs to know the limitations of methods
of use.

Just for the heck of it, I constructed one of these from 1 inch copper, under 12 inches for the 10 meter band, operation at 100 watts. It is on a 20 ft mast and does well for its size--does it rival a 1/2 full physical length? No. <frown>
But, a less than 16 ft vertical omni on 160 meters is an interesting antenna--and one which could almost replace your coffee table book as a conversation piece... <grin>

Source record: 78560

Very interesting post Reg
I see gain figures in Db alone as misleading
since one isn't aware if lobe thickness (and elevation angle) is taken into
consideration.
As Ian points out, comparison to a dipole is fatal since comparison of max
gain inevitably
involves different angles of elevation (I assume that labs take this into
consideration
but I have no proof of it.) As I have stated in the past, different antenna
designs provide
different lobe thicknesses, such that comparisons with each other can
provide higher antenna
gains to the lab's whim if the elevation angle is not taken into
consideration.
Taken to the extreme, all antennas with the yagi design can be declared
equal in gain
when measured at the elevation angle where the leading lobes intersect
Regards
Art

Question -- got a buzz at this QTH; sounds like powerline hash; the
ordinary analogue noise-blankers on my Icom 735 and JRC NRD-525 will
take out the noise, but introduce heavy distortion on the received
signal. Will the the ClearSpeech digital doobies take out the noise
without distorting the signal?

From: RST Engineering <jim@rstengineering.com>
Message-ID: <116npac7lp0a0f4@corp.supernews.com>
Source record: 78564

My internet service provider has established a wireless access point on top of a light pole about a mile from the shack. I'm going to TRY and hit it with a passive repeater (two antennas back to back). I'll use either a caffeine collinear (coffee can reflector) or a popsicle stick yagi on the outside and a plain old dipole inside the shack for reradiation.

My isp doesn't have a clue as to whether is WAP is polarized horizontally or vertically. Does anybody in this ng know for sure whether WAPs or horiz or vert?

Jim

"Naturally, laboratories can differ one from another."

A lab may put its stamp of approval on your instrument, but your best assurance may be measurement of known values. The temperature of ice-water or the voltage of new dry cells, for example You usually can try several dry cells for confirmation or averaging.

In antennas, one strategy for successful gain determination is comparison with an antenna of known gain.

To determine the gain of a SW BC curtain antenna, we hung a 3-wire (to match 600-ohms) folded dipole alongside and at the same height as the curtain. We swiched transmission back and forth every 5 minutes between the dipole and the curtain. We continuously measured and recorded the signal strength for several days in the target area. We averaged strengths of each signal and compared them for periods of the recordings.

The HF dBd of the curtain agreed very well with that measured on the model at 400 MHz in the lab before the curtain was built at full scale.

Best regards, Richard Harrison, KB5WZI

Whow, thats a good idea, write it up for QST. They are looking for pearls of
wisdom
that can be useful for ham radio operators so that we may maintain our
perceived
leadership of the art of antennas......'Compare with a antenna of known
gain'...... Revolutionary!
Now why hasn't any Guru on this group thought of this before today?
Now we have to decide what we use to measure the gain and more important
not to compare or to compare at a single recieving point especially if the
receiving depends
on skip or propagation. Is it possible that Guru's are unaware that
elevation angles
can be different when comparing antennas? Another gem for the ARRL and
provided
solely by the leading gurus of AMATEUR radio operators no less. Ofcourse we
need
a telephone link with the country that we wish to hear the transmission,
some thing on the simple lines of
...."can you hear me now"
question as we switch antennas
between a dipole and a drape / curtain array every 5 minutes

A conical log spiral antenna's radiating plane moves along it's axis with frequency. Various models place the support pole at the rear or at the center of the radiating axis. In any case, use this class of antennas was strongly discouraged after 1996 by MIL-STD-461D.

> ETS-Lingren's antennas are all calibrated at 1m irrespective of frequency.

Your should always calibrate your measurement antenna in accordance with the applicable testing standard. For MIL-STD-461E, this means a 1-meter distance. For commercial emission testing, that means separate calibration tables for 3-meter, 10-meter & 30-meter ranges. And for some conditions, like FCC Part 18 or broadcast station field-strength "footprints", you should obtain a true far-field calibration. Calibration at any distance other than the actual use distance is just not enough.

> Frank (VE6CB)
>

Perhaps the lack of interest in "low frequency far-field" measurements is driven by an absence of any "low-frequency, far-field" compliance requirements? OTOH, MIL-STD-461E is quite concerned with radiated E-field emissions right down to 10 kHz, but at a 1-meter separation distance, this is decidedly near-field! BTW, calibration of this standard's defined 10 kHz to 30 MHz test antenna (an electrically short 41" monopole standing above a small ground plane) is not done on an antenna range! The calibration technique is all conducted, with a known signal being applied by coax, through a shielded 10 pF capacitor, to the antenna input point of the matching network (a box at the base of the 41" rod). The accuracy of the calibration is dependent only on the test lab's ability to read the RF input & output voltages.

When trimmed to SWR, I get less than 1.5:1 on fifteen meters. My
plans are to build a multiband antenna, parallel elements, where each
band is 3/2 wave dipoles and fed with 50 or 75 ohm coax. I haven't
tried this yet, but I would hope I can have a few gain dipole antennas
in a multi-band format.

Richard, fine, so that was the measurement procedure. Thanks for the
description.

Now all we want to know is what was the uncertainty in the
measurement.

Was it within plus or minus x percent? Or perhaps plus or minus y
decibels?

Can you remember the uncertainty approximately?

Or perhaps it didn't matter what the uncertainty was. In which case
it was a waste of time making the measurement.

I presume you realize that a 3/2 wave dipole has multiple lobes, with nulls between. At many or most angles, a half wavelength dipole has greater gain.

You can get just two narrow lobes from a 3/2 wave dipole by rotating the wires 30 degrees to form a horizontal "V" having a 120 degree included angle. I've used this trick with a 40 meter dipole being used on 15 meters -- it doesn't have much effect on the 40 meter pattern. (You'll see some TV antennas made this way for the same reason -- the high TV channels are about 3 times the frequency of the low channels.) But again, if a station isn't in the right direction, you'll do better with a half wave dipole than a 3/2 wave one.

A "gain" antenna isn't of much use if the gain is in the wrong directions. In fact, it's worse than a lower gain one, since the higher gain it gets in a few directions comes at the expense of lower gain in the remainder.

Larry, multiple bonding connections of grounding systems from electrical, RF systems, antenna masts, etc, are rarely guilty of causing the bad-name associated with "ground loop"

Equipment which has either defects or is substandard design and which is daisy-chained in series to a single point ground is a much more likely culprit of AC hum.

Proper single point grounding means each individual piece of equipment has it's own individual bonding conductor to the station single point ground. That is one of the most impractical requirements of proper lightning protection design, and perhaps a rule that is ignored often in favor of a convenient bus-bar behind equipment. But sensitive audio equipment in that daisy-chain, perhaps in concert with an offending radiator bonded on the same bus-bar, could certainly cause an audible problem.

Once a noise-maker is truly grounded (and grounding happens only in the earth, not wherever you make connections in the system, that is bonding),

that noise has very little chance of offending the human ear no matter how sensitive the equipment involved.

Restated:

Earthed system to earthed system bonding does not create ground loops.

Equipment-to-equipment bonding can cause ground loops.

By the way, your system was well described and sounds to be well protected. But you did fail to mention if you have shield-grounded the coaxial feedlines at a number of places, including the tower and before the arrestors. That is a critical part of lightning protection, and arrestors can fail to provide any protection if up to 4,500v that coax can carry is fed to their outer case/body, no matter if that arrestor case is earthed.

Best regards,

Jack Painter

You raise an interesting point. The fact is, it never occured to me, yet is is obvious when you think about it. This implies that at certain frequencies a radiated spurious emission of a certain polarization could be missed. As with conventional log periodics, at any given freqency, a section of the antenna will be active, so I guess you would not get complete rejection. The ETS-Lingren model 3102, has its support pole at the rear, and the 3101 is about 1/3 from the rear. I was not aware of the discouragement in the use of these class of antennas by MIL-STD-461D. Seems pretty sad, when you consider the company I was working for advertised its ATR capability, with no mention made of the MIL standard.

I have seen cal data for 1, 3, 10, and 30m but all are concerned with radiated EMC, and not antenna field strengths, which always was much more interesting. Still the 30 m calibration would be acceptable for most HF work -- at least above 5 MHz.

At 10 kHz it is probably mostly capacative coupling at 1 m.

Sounds like you are talking about a monopole made by EMCO, which had switched frequency ranges. ETS-Lingren (I think they bought out EMCO) now sell model 3301B that has a calibrated antenna factor down to 20 Hz. Must have a very high gain amp, as the antenna factor is only about 25 dB at 20Hz. I have no idea how a cal procedure, using a 10 pF capacitor, can relate the output level to an incident E-field on a 41" monopole. The losses in the matching networks must be very high at the lower frequencies also. Without attempting to analyze such a monopole, the radiation resistance must be in the milli-ohm, to micro-ohm range.

I think not. No "shock and awe" for our U.K. peerless allies.

The U.S. just got a head start on lightning from our Bold Ben Franklin. Luckily he survived. Then, after a Louisiana Purcjase and wars with Mexico and Spain, it won tropical territories which are rife with lightning. I know the sun never sets on the British Empire. It`s just not the same when lightning tradhes some Zulu`s hut as when it strikes your own digs. Lots of Americans live in Tampa-St. Petersburg. This one spot holds the world record for lightning. I think the U.S.A. had more motivation to mitigate the lightning problem.

Best regards, Richard Harrison, KB5WZI

> advertised its ATR capability, with no mention made of the MIL standard.

Everbody loves to argue about antennas; their calibration, application &
accuracy! In the EMC area (my side of the elephant), we are frequently
looking for emissions with a maximum limit so low (imposed by the standard)
that we have to be inside a shielded enclosure. Since the cost of a chamber
increases as the square (or maybe the cube) of its volume, only
extraordinarily well-funded (uhh, governmental) labs can afford really huge
chambers. Thus, most EMC testing happens in more modest volumes (my chamber
is 36' x 24' x 9').

Because the standard recognizes that a lot of the required test frequency
range practically puts the measurements in less than far-field conditions,
the standard gets very picky in defining the acceptable antennas and the
test setup and methodology. Here's what MIL-STD-461E says about conical
logarithmic spiral antennas:

"Previous versions of this standard specified conical log spiral antennas.
These antennas were convenient since they did not need to be rotated to
measure both polarizations of the radiated field. The double ridged horn is
considered to be better for standardization for several reasons.At some
frequencies, the antenna pattern of the conical log spiral is not centered
on the antenna axis. The double ridged horn does not have this problem. The
circular polarization of the conical log spiral creates confusion in its
proper application. Electric fields from EUTs would rarely be circularly
polarized. Therefore, questions are raised concerning the need for 3 dB
correction factors to account for linearly polarized signals. The same issue

is present when spiral conical antennas are used for radiated susceptibility testing. If a second spiral conical is used to calibrate the field correctly for a circularly polarized wave, the question arises whether a 3 dB higher field should be used since the EUT will respond more readily to linearly polarized fields of the same magnitude."

The 41" (or really, 104 cm, gotta get with the program!) the monopole rod goes way back, to the early 50's. It was originally intended to go down to 150 kHz, and the designs (Stoddart, Empire, Fairchild, Singer, AHS, EMCO) were all variations of a 41" rod atop a box containing manually switched transformers. Later designs incorporated remote switching, but these were still passive antennas, with horrible efficiency and high antenna factors/

A big change happened in the early 70's, when active designs came out. The 41" rod was still there (some designs added a big capactive top-hat for greater pick-up), but it now stood on a switchless box that had a very high input impedance FET. (Don't touch that rod; ESD!) But this design allowed antenna factors to approach 0 dB, and yielded a flat gain across 11 octaves! (That nice for automated acquisition systems.)

OTOH, these may not really be antennas any more. They certainly can't be driven with RF power to act as a radiator, so maybe we should be calling them "field probes" instead of antennas.

Since you asked about the rod calibration procedure, here's some background on it, again from MIL-STD-461E:

"There are two different mounting schemes for baluns of available 104 centimeter rod antennas with respect to the counterpoise. Some are designed to be mounted underneath the counterpoise while others are designed for top mounting. Either technique is acceptable provided the desired 0.5 meter electrical length is achieved with the mounting scheme. The 10 pF capacitor used with the rod antenna in 5.16.3.4.c(3) as part of the system check simulates the capacitance of the rod element to the outside world. With the rod antenna, the electric field present induces a voltage in the rod that is applied to the balun circuitry. One of the functions of the balun is to convert the high impedance input of the antenna element to the 50 ohm impedance of the measurement receiver. The 10 pF capacitor ensures that the correct source impedance is present during the check. Some antennas have a 10 pF capacitor built into the rod balun for calibration purposes and some require that an external capacitor be used. For measurement system checks, establishing the correct voltage at the input to the 10 pF capacitor can be confusing dependent upon the design of the antenna and the associated accessories. Since, the electrical length of the 104 cm rod is 0.5 meters, the conversion factor for the induced voltage at the input to the 10 pF capacitor is 6 dB/m. If the limit at the measurement system check frequency is 34 dBuV/m, the required field level to use for measurement system check is 6 dB less than this value or 28 dBuV/m. The voltage level that must be injected is:
28 dBuV/m – 6 dB/m = 22 dBuV

Since the input impedance at the 10 pF capacitor is very high, a signal source must be loaded with 50 ohms (termination load or measurement receiver) to ensure that the correct voltage is applied. A "tee" connection can be used with the signal source connected to the first leg, the 50 ohm load connected to the second leg, and the center conductor of the third leg connected to the 10 pF capacitor (barrel referenced to the balun case). Sometimes a feed-through accessory that acts as a voltage divider is supplied with a rod antenna for the purpose of determining antenna factors. The accessory usually includes the required 10 pF capacitor inside the accessory. If the accessory is used for injecting the measurement system check signal, caution needs to be observed. Since the accessory is intended for only determining antenna factors, the procedures provided with these accessories may not address the actual voltage that appears at the 10 pF capacitor. The design of the accessory needs to be reviewed to determine that the correct voltage is obtained. For a common design, the voltage at the capacitor is 14.6 dB less than the signal source level and 5.0 dB greater than the indication on the measurement receiver."

Whew! That's why I'm glad I only use, and not design or calibrate, those things!

1316. Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-24 23:50:13 UTC
From: Peter <vachonpierre@sympatico.ca>
Message-ID: <SgWae.1437$gA5.108586@news20.bellglobal.com>
Source record: 78482

Hi there, I have a Drake R8B radio and I am not getting the most out of it because of the antenna. I have a 80 foot lot and want to improve my current antenna setup. Right now I have 50 feet of wire strung between 2 trees 6 feet off the ground which I twisted a feed in line in the center of the length. I was wondering if I raise the antenna if it would make a big difference and also I can lengthen it if it doesn't need to be straight I.E. 90 degrees around a tree. Where should I connect the feed in line(I am thinking of using coax)? Also how do I connect the wires? Ground and center.

I realize these might be stupid questions but I am very new to doing this.

Thanks very much for your help.

Interesting comments Roy
But it does utelize the use of dipoles that are not straight but angled. It is well known that pointed /angled dipoles does have advantages such as reducing rotational area, reduction of
reactances that can lead to as much extra gain as 1 Db together with a broader
banded antenna.
In this particular case he has achieved an extra 3 db by stacking.
Your point regarding direction of main lobs is quite important but lessens in importance if the antenna is rotatable. Unfortunately I searched the web page of this new antenna but was unable to find any antenna patterns, which puts one in a "believe it or not" situation regarding its capability versus claims.

Yes, I believe it has four major lobes and a few minor lobes as well.
None are exactly perpendicular to the wire (IIRC).

You got me on this one. I haven't looked into the 'V-Beams'. I was
thinking they were 1/2 wave dipoles. TV antennas are also a form or
Log-Periodic aren't they?

Yes, this is a form of compromise antenna. I guess if I were looking
for the perfect (omni) antenna, it would be a loop.

Many hams use G5RVs or tuned dipoles cut for their lowest desired
band. While they all work, they all have their lobes on certain
bands, probably each band with different lobes.

I realize that the antenna will have nulls and lobes. If possible, I
would want to arrange the antenna in such a way as to use the lobes to
my benefit. Primarily, it is an experimental antenna as much for the
fun of building it as for using it.

I also plan to build a multi-band beam, but not right away.

Thanks for the input. I'll check into the 'V' antenna.

Buck could get a good idea of the radiation pattern using
EZNEC (even the free downloadable version from www.eznec.com).

And the higher & longer you make it, the more you need to have a grounding antenna switch. Leave the antenna grounded when not in use - and don't use it when there are electrical storms nearby. Note: Grounded antennas are less likely to get struck directly than floating wires because they will drain off a static charge that might actually attract the lightning. Also, most receivers are damaged by "close" strikes, not direct hits - and the grounded wire will take care of the induced current easily. On a direct hit, it may do the job, but insurance is always good to have.

Hi Jim,

I don't "know," but given that the WA of WAP suggest strongly of
maximum coverage (which is antithetical to horizontal gain antennas
with nulls), vertical polarization would seem a good bet.

This does not limit you to having a vertical gain antenna (with
nulls), in fact it could be a speed advantage (cutting down on phase
errors lowering through-put). Simple enough to tilt your antenna to
find out which orientation does the job (once you know where the base
station is, that is).

Dear Andrew:
Your message has languished for a while.
Why would one wish to perform the suggested mutilation? The instrument
works fine just as it is.
Among the available instruments for measuring antenna and transmission
line impedances that are not a long way from 50 ohms, I have found the CIA
to be the most useful.

Cross-posted to:
rec.radio.amateur.antenna,alt.sports.football.pro.tampabay-bucs,alt.tv.simpsons,news.software.readers,alt.fan.furry

This is the most important question of your life.

The question is: Are you saved?

It is not a question of how good you are,
nor if you are a church member, but are you saved?

Are you sure you will go to Heaven when you die?

The reason some people don't know for sure if they
are going to Heaven when they die is because they
just don't know.

The good news is that you can know for sure that
you are going to Heaven.

The Holy Bible describes Heaven as a beautiful
place with no death, sorrow, sickness or pain.

God tells us in the Holy Bible how simple it is
to be saved so that we can live forever with Him
in Heaven.

"For if you confess with your mouth Jesus is Lord
and believe in your heart that God raised Him from
the dead, you WILL BE SAVED." (Romans 10:9)

Over 2000 years ago God came from Heaven to earth
in the person of Jesus Christ to shed His blood
and die on a cross to pay our sin debt in full.

Jesus Christ was born in Israel supernaturally to
a virgin Jewish woman named Mary and lived a sinless
life for thirty-three years.

At the age of thirty-three Jesus was scourged and
had a crown of thorns pressed onto His head then
Jesus was crucified.

Three days after Jesus died on a cross and was
placed in a grave Jesus rose from the dead as Jesus

said would happen before Jesus died.

If someone tells you that they are going to die and
then three days later come back to life and it
actually happens then this person must be the
real deal.

Jesus Christ is the only person that ever lived a
perfect sinless life.

This is why Jesus is able to cover our sins(misdeeds)
with His own blood because Jesus is sinless.

The Holy Bible says, "In Him(Jesus) we have
redemption through His blood, the forgiveness of
sins..." (Ephesians 1:7)

If you would like God to forgive you of your past,
present and future sins just ask Jesus Christ to be
your Lord and Saviour.

It doesn't matter how old you are or how many bad
things that you have done in your life including
lying and stealing all the way up to murder.

Just pray the prayer below with your mouth and mean
it from your heart and God will hear you and save you.

Dear Jesus Christ, I want to be saved so that I can
have a home in Heaven with You when I die. I agree
with You that I am a sinner. I believe that You love
me and want to save me. I believe that You bled and
died on the cross to pay the penalty for my sins and
that You rose from the dead. Please forgive my sins
and come into my heart and be my Lord and Saviour.
Thanks Lord Jesus Christ for forgiving me and saving
me through Your merciful grace. Amen.

Welcome to the family of God if you just allowed God
to save you.

Now you are a real Christian and you can know for
sure that you will live in Heaven forever when this
life comes to an end.

As a child of God we are to avoid sin(wrongdoing),
but if you do sin the Holy Bible says, "My dear
children, I write this to you so that you will not
sin. But if anybody does sin, we have one who speaks
to the Father in our defense Jesus Christ,
the Righteous One."

Those of you that have not yet decided to place your
trust in the Lord Jesus Christ may never get another

chance to do so because you do not know when you
will die.

Jesus said, "I am the way, the truth and the life:
no one can come to the Father(God)(in Heaven), but
by me." (John 14:6)

This means that if you die without trusting in Jesus
Christ as your Lord and Saviour you will be forever
separated from the love of God in a place called Hell.

The Holy Bible descibes Hell as a place of eternal
torment, suffering, pain and agony for all those who
have rejected Jesus Christ.

The good news is that you can avoid Hell by allowing
Jesus Christ to save you today. Only then will you
have true peace in your life knowing that no matter
what happens you are on your way to Heaven.

Praise the Lord!
Servant of the Lord Jesus Christ
Ronald L. Grossi

Actually the most important question of your life is:

Are you capable of acting like a rational human being long enough to understand that all you are doing is proving that while Jesus may have been a radical socialist, who hung out with prostitutes and drank with his friends, some of his followers are complete dickheads.

...Brock.

Hi Tom,

Yes, BEAUTY!! ;) Well, we could have been faced with that "S" word.
No, not the stuff you step in, the stuff you have to shovel. Oh, wait.
Both "S" words fit that description. I was working in Hayward on
Friday and we were having a white-out from the "S" word. Hard to
believe it was 80 just one week before Aurora.

Actually, I'm quite pleased with the Quagi. It appears they outperform
(most) Yagis (at least in gain) with equal numbers of elements. The
loop driven element also seems to help with noise pickup too. It seems
to be a quieter antenna than my Yagis. Running QRP on 432, I'll take
and radiation I can get, even if it's from the feedline ;) (That's my
omni-direction part of my antenna so I can hear others calling and then
I can swing the antenna!!)

I would guess vertical. Most wireless cards or routers for home use
have their antennas vertical. Probably a little easier to make it
omnidirectional too...

Hey Ralph,

If you have access to an MFJ 259 type antenna analyzer with the 440 band
included, it makes it a piece of cake to get a match. What I did was
pull out the first director and laid it on top of the wooden boom and
moved it forward until I achieved the lowest SWR, which was 1.2:1.
Never did alter the size of the driven loop. May screw up the patter or
efficiency, but I don't have a good way to measure either, so I didn't
give much of a hoot...just wanted to make the radio happy so it pumps
out full power ;)

Thanks for the words of encouragement...think I'll try a 222 version...

Ron
Why are you trying to get people angry with Bible talk thrust into their
faces
and their homes. Are you trying to get people so angry that they turn
against the bible
instead of being angry at you?
Why is it that you feel by making people angry at your tactics is a service
to
your religeon such that it will further a deeper belief?
Since you are placing the seeds of anger indiscriminatly across many groups
assembled
for discussions of their choice, which are different to your own, it would
appear
furtherance of your religeon is not your desire since a similar disruption
of your own
flocks discussions would not be met very kindly by the congregation.
Save and cherish what you have instead of wasting time with those you don't
have,
by evoking anger instead of examplary behaviour following what you suggest
you represent.
Nuff said...no response necessary, this thread is now absent from my
interests
Art

<RonGrossi382876@yahoo.com> wrote in message
news:1114394688.099945.218580@z14g2000cwz.googlegroups.com...

This is the most important question of your life.

The question is: Are you saved?

It is not a question of how good you are,
nor if you are a church member, but are you saved?

Are you sure you will go to Heaven when you die?

The reason some people don't know for sure if they
are going to Heaven when they die is because they
just don't know.

The good news is that you can know for sure that
you are going to Heaven.

The Holy Bible describes Heaven as a beautiful
place with no death, sorrow, sickness or pain.

God tells us in the Holy Bible how simple it is
to be saved so that we can live forever with Him
in Heaven.

"For if you confess with your mouth Jesus is Lord
and believe in your heart that God raised Him from
the dead, you WILL BE SAVED." (Romans 10:9)

Over 2000 years ago God came from Heaven to earth
in the person of Jesus Christ to shed His blood
and die on a cross to pay our sin debt in full.

Jesus Christ was born in Israel supernaturally to
a virgin Jewish woman named Mary and lived a sinless
life for thirty-three years.

At the age of thirty-three Jesus was scourged and
had a crown of thorns pressed onto His head then
Jesus was crucified.

Three days after Jesus died on a cross and was
placed in a grave Jesus rose from the dead as Jesus
said would happen before Jesus died.

If someone tells you that they are going to die and
then three days later come back to life and it
actually happens then this person must be the
real deal.

Jesus Christ is the only person that ever lived a
perfect sinless life.

This is why Jesus is able to cover our sins(misdeeds)
with His own blood because Jesus is sinless.

The Holy Bible says, "In Him(Jesus) we have
redemption through His blood, the forgiveness of
sins..." (Ephesians 1:7)

If you would like God to forgive you of your past,
present and future sins just ask Jesus Christ to be
your Lord and Saviour.

It doesn't matter how old you are or how many bad
things that you have done in your life including
lying and stealing all the way up to murder.

Just pray the prayer below with your mouth and mean
it from your heart and God will hear you and save you.

Dear Jesus Christ, I want to be saved so that I can
have a home in Heaven with You when I die. I agree
with You that I am a sinner. I believe that You love

me and want to save me. I believe that You bled and
died on the cross to pay the penalty for my sins and
that You rose from the dead. Please forgive my sins
and come into my heart and be my Lord and Saviour.
Thanks Lord Jesus Christ for forgiving me and saving
me through Your merciful grace. Amen.

Welcome to the family of God if you just allowed God
to save you.

Now you are a real Christian and you can know for
sure that you will live in Heaven forever when this
life comes to an end.

As a child of God we are to avoid sin(wrongdoing),
but if you do sin the Holy Bible says, "My dear
children, I write this to you so that you will not
sin. But if anybody does sin, we have one who speaks
to the Father in our defense Jesus Christ,
the Righteous One."

Those of you that have not yet decided to place your
trust in the Lord Jesus Christ may never get another
chance to do so because you do not know when you
will die.

Jesus said, "I am the way, the truth and the life:
no one can come to the Father(God)(in Heaven), but
by me." (John 14:6)

This means that if you die without trusting in Jesus
Christ as your Lord and Saviour you will be forever
separated from the love of God in a place called Hell.

The Holy Bible descibes Hell as a place of eternal
torment, suffering, pain and agony for all those who
have rejected Jesus Christ.

The good news is that you can avoid Hell by allowing
Jesus Christ to save you today. Only then will you
have true peace in your life knowing that no matter
what happens you are on your way to Heaven.

Praise the Lord!
Servant of the Lord Jesus Christ

Yes, I especially like the "ease of build" feature and it was very easy
to get a good solid antenna connector mounted. That always seems to be
the weak point of most homebrew antennas...the feed is usually so
flimsy, I'm afraid to throw the antenna in the back of the truck to haul
it to a portable operating site!

Amen brother! There may be better designs, but the Quagi has to be near
the top in the catecories you mentioned, and I agree with everything you
said. Besides, the proof is in the pudding...106 miles on 5 Watts!
Almost unheard of around here (Wisconsin). I'd be pleased with that for
sure!

Well Art, as much as people may desire some sort of definitive "this
antenna performs exactly as....." statements, it would seem that they
aren't going to get them.

Which is to say that Richard's statement IS a pearl of wisdom, despite
being unsatisfactory in some peoples view.

Well, I did cheat a little bit - was up a couple thousand feet on a
mountain. If you're interested and have a good atlas or online map
service, my location is the LA area and the repeater is located pretty
darn close the intersection of the 405 and 105 freeways and I was
located close to the intersection of the 14 and 395 highways.

Now get busy and build the 222 mHz version 8-}

Richard,
You state that you used a dipole to compare with, which was at the same
height !.
Which antenna was altered so that the elevation angle of maximum gain
was the same for both antennas.such that max gain measurements
were truly comparable?
Where was the height of the "curtain" measured or referred to
so that "same height" could be justified ?
(You also did say it was for SW use which is certainly different
to ground wave use)
Presumably, the comparison was for the same type of polarization
and ignored differences created by the side addition of other
types of polarization.
Without further information the "Facts" could be seen as
correct to plus or minus 100 percent measurement error!
An expert in the field of measurements such as Richard could have a field
day
disecting the test mode as discussed by you and certainly does not reflect
the
professional antenna analysis aproach which Reg is seeking., which, most
certainly,
would take into account the elevation angle at which maximum gain occurs
as well as many other things

At 3/2 wavelengths, there are lobes perpendicular to the wire, but
they're down around 4 dB relative to the maximum lobes.
>
> You got me on this one. I haven't looked into the 'V-Beams'. I was
> thinking they were 1/2 wave dipoles. TV antennas are also a form or
> Log-Periodic aren't they?

The 3/2 wave antenna bent into a "V" with 120 degree included angle is a
form of the "V beam", similar to half a rhombic. As the antenna gets
longer, the angle of the "V" has to get more acute to make the lobes
align. You can use the "V" shaped elements to make a Yagi, log periodic,
or other array. TV antennas are often a combination of those two.

Nothing at all wrong with that. It'll be both fun and educational. You'd
also have fun with an antenna modeling program, which would let you see
the kinds of patterns you'll get.

Mike,
Do you really believe that Reg is really unaware that "comparing
with a dipole" can be used by some (as long as all parameters are stated
specific and to the point) ? If Richard really thought that comparing to a
dipole was unique
Richard surely should have added more data. Thus the reason that Richard
brought forth
this item of wisdom forward in answer to Reg,s initial post, which was quite
clear,
is unfathomable without a "grin" additive to declare his true intent was not
to be facitious.

Especially since it did not add details which pertained to professional
antenna.
measurement methods as requested by Reg which is part and parcel of
ascertaining
degree of error that was specifically referred to.
As an aside it would appear that statements above made by Richard have been
atributed to Reg which certainly muddies the waters to which you refer to.

Source record: 78513

Hello Mac!

Thanks for the response.
The CIA has one problem which is that it is very sensitive to ANY RF
in the vicinity and I have so much going on in the shack that it
simply does not function there. I have to go out to the antenna
switching system at the bottom of the tower (very cold) to measure
antennas. I had heard that there is a simple modification which
increases the output to overcome this problem, and it also improves
the accuracy.

So if anyone has a schematic or could tell me which resistor needs
reducing in value I would be happy - and warmer too!

What Brand would you recommend and why?
Brands include:

Quickstick from Quicksilver Radio
Lakeview
MFJ
Valor/Proam

Any real world experiences with any of the above antenna's.

The "hamstick" would be used for a NVIS ARES emergency dipole on 75m
and 40m. And yes, I know about the bandwith and effeciency. This
would be a temp, portable, emergency antenna.

1352. G5RV vs. Half Square on 20m

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-25 10:13:53 UTC
From: "Chuck W." <cwyatt@w3minds.com>
Message-ID: <1114424033.282884.32850@o13g2000cwo.googlegroups.com>
Source record: 78517

I understand that strictly speaking a G5RV isn't a multi-band antenna,
but my primary use of it is on 20 meters where it works pretty well as
a 3/2 half-wavelength doublet. It's up about 55 feet now as a flat-top
and I've been working plenty of DX with only about 300-400 watts out.

Never satisfied, and always wanting improvement (it's a compulsion!),
I'm wondering whether a half-square like the Windom HSQ listed here
would be an improvement on 20 meters:
http://www.antennasmore.com/windomhq.htm

I've read that at 20 meters and above, there is more benefit to being
horizontally-polarized at a decent height, so maybe I'm better off with
the G5RV?

Thanks for any thoughts.

Hi Chuck,

Cebik conclueds the following when speaking of the Half Square antenna.

" Installing SCVs too high, especially half squares, can easily defeat
the main functional advantage of the antennas. Designing them for 20
meters is a marginal enterprise, and above 20 meters, other antenna
types will normally out-perform the SCVs. The SCVs do come into their
own again until the VHF region, where they can be mounted many
wavelengths above ground and their largely vertical polarization
combined with a beamwidth around 60 degrees may be superior in some
applications to Yagis turned on their side.

Except for these very general comments, I have avoided comparisons with
other types of antennas. Although a thorough comparison would be useful,
the amount of material there is to present on SCVs and the shortage of
space within which to present it suggests that this must be (as they
sometimes say in textbooks) "an exercise left to the reader." --Cebik.

you can read the whole article at :

http://www.cebik.com/scv/scv4.html

My best guest is that at 55 feet the G5RV is a better all round antenna
on 20 Meters.

Source record: 78521

Okay, so here's a slightly-off-subject follow-up. I looked thru
cebik's web site and didn't see this addressed: Since the G5RV isn't
particularly resonant on 17 and 15 meters, if I connected a dipole for
each of these bands, in parallel, at the same feedpoint as the G5RV
would this work effectively?

Way back when, I recall putting multiple dipoles at the same feedpoint
without incident, but I haven't really seen this discussed much.
Intuition suggests that they would interact negatively and impedance
would be wacky.

I like the Iron Horse antennas for mobile work because it is easy to break them down for storage. You can leave the whip portion set to the proper length since it's held in place by a set screw in an easily removable fitting (just requires fingers or pliers). The Hamsticks work well, but to break them down you need to loosen the setscrew with a greater chance of losing it and the necessity to reset the length when you re-assemble the Antenna.

I use the Iron Horse. Ive used the Hustlers and the Pro-Ams before.
And for me on my installtions the Iron Horse have proven to be the
widest bandwidth and best signal peformance out there. I dunno why. I
put them on the bed with a stake mount. Ive always been asked if Im
running a screwdriver. When I was county hunting Ive many good comments
as a mobile about my signal.

They work for me and I wouldnt have any other brand.

(no I dont work for them, Im just a very satisfied customer)

One thing I have found quite useful about some brands
is the 3/8"x24 connector at the *TOP* of the coil
section that holds the stinger. I don't remember what
brands that is but they have two 3/8"x24 connectors,
one on each end of the fiberglas section. For instance,
I can install another loading coil between the hamstick
coil and the hamstick stinger.

I have a Valor 40m and a Lakeview 20m. The 40m didn't tune up without a base loading coil, but worked great with it. Also worth noting is that my Lakeview flew off the back of my van at 70mph when my magnet mount -came unglued-.. The magnet stayed on the roof while the chrome housing and antenna took flight. I dragged it for a few hundred yards, and it's not as pretty now, but still works fine.

> http://www.antennasmore.com/windomhq.htm

Suggest you obtain a copy of EZNEC (free demo available at
www.eznec.com) and observe the radiation patterns. In a
nutshell, the G5RV will outperform the HSQ in four directions.
The HSQ will outperform the G5RV on 20m in the directions of
the G5RV pattern nulls on 20m because the HSQ distributes the
RF energy differently. From their web page, the HSQ radiation
pattern looks more like a vertical on 20m. So the answer is:
In some directions, you will be disappointed with the HSQ. In
other directions, you will be satisfied with the HSQ. I
personally don't see how you would ever be satisfied with
the price of the HSQ. :-)

That's what antenna modeling programs are good at. There
would probably be some interaction on the higher bands.

"If Richard really thpoght that comparing to a dipole was unique."

Not at all. I was relating an experience which I hoped was accurate and useful.

Kraus describes the "comparison method" on page 857 of his 3rd edition of "Antennas". I used the reverse of his example, switching transmitting antennas instead of receiving antennas.

Kraus` volume goes into many details of antenna testing.

Best regards, Richard Harrison, KB5WZI

Cecil,
That is the exact problem I have with my antenna which comprises of
reflectors only(no directors) that are manipulated in shape to reduce
reactance swings. Expect to have another shot at it sometime this week
It was easier to put up a long boom with 13 elements or a duplicate antenna
where the reflector elements were not manipulated in shape than this present
experimental antenna.
But even a fraction of a dB gain increase becomes an magnet
for a experimentor.
As for your 180 metre form could one not borrow a Tee shaped
crane from a building site and place elements along its boom ?
I'm sure that would be strong enough to rotate in safety.
Regards
Art

Last place I worked with EMC facilities they only had a 3 m cube chamber.
The dimensions you quoted are huge compared to my experience. (I think ETC,
in Airdrie Alberta, had a similar chamber to yours; also General Dynamics in
Calgary had two similar chambers. Also Nortel has some EMC capabiltiy.)
The insides were covered in microwave absorber, and there was some question
as to how effective the absorber was at 30 MHz. It must have done
something, since before the absorber was installed it was interesting to see
the effects on a transmitter keyed inside a shielded enclosure.

Very interesting Ed, will forward your comments to my last company. Doubt
they will do anything tho, as they never want to spend any money. Assume

the recomended type of antenna is a linearly polarized log periodic.

I remember the Singer (Was it Singer-Metrics), and using it to measure radiated spurious in a cow pasture at 50 m from a 1kW TMC linear (Canadian Marconi, Montreal). The test monopole had a cylindrical base with a rotary switch.

It does seem a bit confusing. I have never seen this procedure before, and
do not understand how a physical length of 1.04 m can have an electrical
length of 0.5m. I guess the 10pf capacitance of the rod is its capacitance
with a defined ground plane size. I don't think I would be 100% convinced
as to the procedures accuracy unless I could verify it with a known E field.
At least, in principal, I understand what is being done.

1375. HFTA and NED data

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-25 17:39:22 UTC
From: Bill Ogden <wogden@attglobal.net>
Message-ID: <BW9be.11942$V02.7197@fe08.lga>
Source record: 78390

I am trying to use the HFTA program in the latest Antenna manual. I printed the instructions from the CD and attempted to download NED data from the seamless.usgs.gov site. It appears that the usgs people have "improved" their web site since the instructions were written. I played with the site but was unable to download anything that would work.

My PC screen resolution is 1280x1024 with 16-bit color. (I think this is relevant.)

I receive the first page of the usgs site and select the map of the United States. The next page has a large rectangle in the middle where a map should appear (I assume) but it remains blank. I cannot find a place to select RASTER=NED, as specified in the HFTA instructions. I could input a coordinate box and then download a zip file, but MicroDEM rejected the file as not containing valid data.

Are there any updated instructions for obtaining the NED data?

The topic on ground rods has awakened a concern that has been at the back of my mind for some time and I would be grateful for your suggestions, folks.

What measures, beyond un-plugging the antenna from the equipment in the shack is recommended to prevent damage from static and lightning damage?

Rob (M0LET)

> would this work effectively?

I had dipoles cut for 40, 17, and 12 m all in parallel, and it works fine, so long as you can get several feet of separation between the ends of the dipoles and the other wires. Just tune the highest frequency antenna first and then work down. This was for a 50 Ohm feedline. A real G5RV uses 1/2 wavelength at 20 m of 450 Ohm line; this is transparent at 20 m, but makes the antenna usable on 80. The 450 Ohm line would probably mess up any parallel dipoles you hang across the G5RV.

1379. Re: G5RV vs. Half Square on 20m

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-25 18:02:05 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <d4jbat$6p3$3@nwrdmz03.dmz.ncs.ea.ibs-infra.bt.com>
Source record: 78394

The performance of a G5RV as a multi-band dipole, because of its length of coax feedline, is somewhat worse than any other random length of dipole fed with a random length of feedline of random impedance.

Remove the coax, bring the feedline all the way back to the shack, and the G5RV is just as good as any other simple multi-band, multi-directional antenna.

As with other random length antennas a tuner is always useful.

Reg. G4FGQ.

|
|Whow, thats a good idea, write it up for QST. They are looking for pearls of
|wisdom
|that can be useful for ham radio operators so that we may maintain our
|perceived
|leadership of the art of antennas......'Compare with a antenna of known
|gain'...... Revolutionary!
|Now why hasn't any Guru on this group thought of this before today?

Perhaps because it's so commonplace that it doesn't bear mentioning.

|Now we have to decide what we use to measure the gain and more important
|not to compare or to compare at a single recieving point especially if the
|receiving depends
| on skip or propagation. Is it possible that Guru's are unaware that
|elevation angles
|can be different when comparing antennas? Another gem for the ARRL and
|provided
|solely by the leading gurus of AMATEUR radio operators no less. Ofcourse we
|need
|a telephone link with the country that we wish to hear the transmission,
|some thing on the simple lines of
|...."can you hear me now"
| question as we switch antennas
|between a dipole and a drape / curtain array every 5 minutes

If you believe that precision antenna gain measurements are made under
ionospheric propagation conditions, you are clearly delusional. But I
repeat myself.

>
>Hi Joe,

I have been reading the responses to your request for help with interest.

Perhaps I should have paid more attention to your wording and been more careful in my response. Though my intention was never 'to teach a hen to suck eggs'.

My answer, I believe, was correct as far as RF is concerned. This should be isolated as far as possible from the domestic supply to avoid EMC/RFI issues.
I should have stressed, however, (eggs and hens beware, here) - All mains-powered equipment must be earthed for safety reasons. The only exception to this rule is where equipment is 'double insulated' - otherwise it must be earthed using the earth pin in the 3-pin mains plug.

'The RF earth is there to divert RF currents away from the mains earth and safely down to ground. It consists of one or more earth rods driven into the ground, preferably in damp soil.. These rods aremade for the purpose and are available from both amateur antenna/feeder suppliers and good electrical suppliers dealing with the trade and local electricians. These rods are some two meters long and are usually made from cooper-coated steel. They should be hammered into the ground close to the shack, taking care to avoid hidden services and drainage pipes. A heavy cable should be clamped to the rods and connected directly to the transmitter or AntennaTuning Unit.' The RSBG guide to Good Radio Housekeeping then refers to a figure showing a typical arrangement.

Also suggested is keeping any mains leads as short as possible and the low voltage DC power leads should be fitted with ferrite rings as close to the equipment as possible.

Mains-born interference can be a significant problem in a densely populated country such as the UK and as such is given a high profile in the RAE.

This topic has brought to mind something that has been nagging me for some time. Please see my posting on lightning.

Rob.

That's what I thought. So why did Richard say it unless he felt that Reg's
education in antennas was a bit lacking. Reg's question was specific and of
high caliber
Richard's answer tried to bring it down to a level for dummies which did
not begin
to reflect on the question posed

>

Yes ,,,a big "IF" isn't it?
But you could supply the info Reg was looking for since you
perceive yourself as a GURU .
It would be much more rewarding to the group as a whole than
picking out somebody to demean.My point is that a gain figure alone
is meaningless unless the elevation angle differences or perhaps a
3 dB window comparison are also supplied.
If you think otherwise I would welcome a technical response
rather than something lead by emotion

Yes, there is a revised manual to replace the one on the CD. Go to
www.arrl.org and search for HFTA.

Charlie,

Thanks for the review....I have one of the older versions...an AmCom speaker/ DSP combo...and wanted to give my "unbiased" input.

The speaker does take out some noise but, unfortunatley I cannot give it the same "unworkable to arm chair copy" review you have. I've used this with my MP, MP Mark V and currently with my mobile FT100D. All experiences have been the same; mediocre. There were few instances where the AmCom alone made a signifcant difference.

The voice quality is very degraded when the DSP is engaged and the audio level drops substantially and has a "talk in a barrel" quality. Having one of the earlier models, I found the heavily engaged, non-variable DSP to be quite annoying. Also, I found that the unit is definitely NOT required if you use the internal DSP of the rig. Yaesu DSP and noise reduction are more effective than the AmCom.

This is the second unit I've tried, having thought the first to be defective. AmCom was nice enough to replace the first.

Additionally, I see you found out that the unit is RFI prone. Remarkable that this should be the case for such as expensive accessory that is supposed to be functional in an RF environment.

In short, Good Luck with the unit....and thanks for the review....

Source record: 78401

Hi Bill

I have also found seamless to be a little less intuitive than it all use to be. I was only just trying to get a hold of some raw SRTM data and find that they dont. (There is an FTP site still avail tho) However I found a nice easy way to drive the website. I apologise if I am repeating what you have already tried.

- From the main page click on the US. When the viewer comes up click on the second button under "Downloads" (control bar mid LHS). This is "Define area by Co-ordinates"

- In the popup window that arrives (make sure you have allowed popups for this site on your web browse - if such a limitations exist) enter the co-ordinate limits of your requirement. Change to Decimal degrees as needed. Then click on the Add Area button.

By default it tries to give you NED in ArcGrid format as a zip file. If you click on "Modify data Request" you can change the kind of data you are downloading. I suggest you check what kind of format the HFTA pgm needs.

Whatever you select it then packs up (can take maybe 30 secs) and downloads to your PC. Obviously you have to unpack it to use it.

My PC also has a large blank rectangle when I go to the viewer. I had assumed it was my setup and was going to get aorund to fixing it.. Only I wont now! All other USGS map etc sites seem to be fine so I suspect there is a server problem. (I use Firefox 1.01 SuSE Linux 9.1 Prof)

Cheers Bob VK2YQA

not good enough! voltages on the ground can damage the equipment just as
fast as from the antenna. you must either disconnect all wires connected to
the radio or make sure everything is grounded and has proper arresters
installed to be sure.

Art Unwin wrote:
"My point is that again figure alone is meaningless unless the elevation angle differences or perhaps a 3 dB window comparison are also supplied."

Reg knows very well that a quantity is determined by comparing it with a known standard.

The power gain of a resonant dipole in free-space is given by Terman on page 871 of his 1955 edition as 1.64.

Kraus agrees on page 54 of his 1950 edition and converts Terman`s power gain of 1.64 to 2.14 dB (referenced to an isotropic).

The values given by Terman and Kraus are accepted.

Horizontal antennas at the same heights tend to have similar elevation angles, but even if they didn`t, comparison of the signals our two antennas laid on the target represented our interest in the matter.

What we confirmed was that the new curtain antenna had a gain comparable with our rhombics but over a wider beamwidth which meant listeners on the edges of our coverage got a better signal with the new curtain antenna.

The bandwidth was less than a phombic so the curtain meant more work for the operators, but the broadcasts were for the listeners` benefit.

Signal strengths were measured at many locations around the target area to define the coverage of the antenna pattern.

Best regards, Richard Harrison, KB5WZI

It would be best if NO antenna connection is in the shack during a lightning storm... I live where such storms are few and far between--still, I make sure ALL ant connections terminate outside the shack (to ground), and there are NO live antenna connections in the shack (no coax, leadins have connections to an ant AND which terminate in the shack.)
Being accused of being paranoid rolls off my shoulders as water off a ducks' back...

As stated by Ian, there's no simple answer. The bane of antenna
testing is reflections reflections reflections.

It may come as a surprise to our correspondent who likes to disparage
"gurus" that "standard-gain" antennas are widely used as reference
standards. To head off the question of how the standard gain is
determined, that is done by testing three "identical" antennas in
pairs; each one against the other two, with one the source and the
other the receiver. A bit of algebra and you have the gain of each
one individually.

http://www.mi-technologies.com/literature/a00-044.pdf

The foregoing paper might help answer Reg's question about achievable
accuracy.

While not addressing hf and vhf measurements, some of the following
might be of interest.

Indoor measurements are usually conducted in anechoic chambers where
the shape is often tapered to control reflections and the walls are
covered in absorber material. A chamber will have a "quiet zone"

where the reflections are specified to be X db down. Very often the antennas under test are being characterized for side lobe levels or in the case of monopulse radar, the null depth of the difference pattern(s). If you're trying to measure a 60 dB null, it doesn't pay to have a quiet zone of -40 dB.

These measurements also require an amplitude and phase front that mimics a source at infinite distance. This used to require huge chambers, often hundreds of feet long. A new way to accomplish this is to "fold" the range by using specially shaped reflectors to flatten the amplitude/phase across the test aperature. This has the added benefit of shorter cables between sources, DUT and measurement receiver. At X and K band, cable loss can be a killer. Likewise moving cables around and even temperature changes can affect the measurments.

I have used such a range to measure antennas from L to Ka band.

Outdoor ranges often "feature" the ground reflection, since it is difficult to eliminate it physically. This is particularly true at hf/vhf. I have used a technique that utilized the time-domain capability of a modern network analyzer (HP-8510) to identify the reflection and then place absorber material to attenuate it. Similarly, a frequency-domain measurement, that includes ground reflection, can be transformed to the time domain where the reflection is gated out and then transformed back to the frequency domain for "reflection free" analysis.

I am using Antenna Specialists antennas on my car. They have the
connector where the stinger plugs in. I can also add another
fiberglass whip on there if I prefer due to the common connector.

Is that the one of which you are speaking?

Dear all,

Mrs. yin,SV7DMC and Mr. pez,SV7BAX of TheDAG
have strongly suggested your newsgroup,
to ask for support, help, comments or opinions
about antennas matters.
Well, I study this prototype antenna:

http://antennas.ee.duth.gr/recradioamateurantenna/dt/2005/kal/07/geo%2Bcomments.gif

Does it remind you of any other antenna?
I want to know if it has been studied by anyone else before.
And I also want to give it a name...
All suggestions welcome!

Thank you in advance.

Wes,
What you have posted is very interesting and is not spewing out alot of
stuff
regarding isentropic gain etc that is really not relevent to an actual
testing range.
Rather than deflect away from Reg's needs may I go back to the "compared to
a dipole"
statement which Richard keeps brushing off. If the gains are different then
the
angle for max radiation is different and if you do not take this into
account by searching
for the individual point of maximum gain position then the the measurements
are in total error.
To put antennas at the same height and then measuring at the same stationary
point for receive,
switching back and forth
is not a true comparison because of the different elevation angles. If one
was to compare a long yagi
to a dipole ando make it a true comparison measurement one must surely take
into account the two degree
or so difference when positioning the listening posts and not relying on a
single
listening position which to me appears to be a NO No .
Richards response to the "error" question totally ignored TOA saying they
are usually
the same . He also ignored what he considered as an "equal" height for the
curtain,
i.e the top,bottom or the center line of the curtain array which alone would
introduce
error with respect to comparible measurement. If Richard was pointing out
that his was a typical
professional method of measurement then I would view his statement in
complete disbelief.
Your posting, thankyou, confirms my thinking in that the use of a dipole
only confirms the reliability
of the set up used and that is the end of it with respect to measurement of
a competing antenna
where I suspect a pro lab would identify the particular resulting elevation
measurement.
If the last sentence is in error I would apreciate a correction
Regards
Art

Yes, it reminds me very much of a modified "hentenna", with matching section
replaced by two of your half-wave dipoles...

Regards,
John

Hi Randy, as you know Hamsticks are dogs above 20m. If you are planning on using them in a dipole configuration on 75m, get the most sturdy. For NVIS ARES emergency dipole on 75M, from my experience other configurations will work much better. Field day experience.

Bob Collis wrote:
"What measures beyond un-plugging the antenna from the equipment in the shack is recommended to prevent damage from static and lightning damage?"

Commercial services don`t shut down when storm clouds gather. They must operate despite lightning crashes.

I began working in broadcast plants in 1949. None had any damage despite frequent direct hits.

First, no lightning made it through a very important item, the tower lighting choke. Every tower lighting wire on the tower, beacon, side lights, and neutral has a winding on a big ceramic coil form.

The tower side of these windings must present a high impedance to the R-F. They have no shunts to ground.

The line sides of these coils have each their bypass capacitors and thyrite arrestors to ground. It nworks. The power line is free from serious transients.

Towers sit on base insulators which are shunted with arc-gaps which rarely if ever fire. Another spot gets all the action. It is the Faraday screen between the primary and sexcondary of an air-cored R-F transformer which couples the tower to the antenna system. The Faraday screen is a comb-like structure of metal fingers grounded securely along one edge. The tines protrude open-circuit into the air like a row of soldiers. Coils share an axis on either side of this metal comb. Surface of this Faraday screen is pock-marked like the surface of the moon. This is where the lightning finds its way to ground.

Lightning gets an inhospitable reception by the transmitter coax too. The inside surface of the shield and the outside surface of the inner conductor have inductance to oppose the lightning (a common-mode current) and these conductors are tightly coupled along their length. Shunt capacitance couples the two surfaces too. A transient trying to make its way down both conductors at once is stiffly rejected.. This usually triggers a flash over. Transmitters usually have a circuit to sense this and it momentarily kills the transmitter to prevent follow through of an r-f arc fed by the transmitter.

Working with VHF transmitters and receivers, I found that the same princoples used on medium wave radios worked very wel at VHF too. No lightning damage to transistorized base stations with antennas at the highest points for miles around.

Best regards, Richard Harrison, KB5WZI

That's true, SWR increases, but how much do you want to operate when
it is raining?

Realistically 90+% of CS students are going to end up in jobs programming web pages, databases, and other applications where it just isn't going to matter. There just isn't time in the curriculum these days to cover everything... For that matter, these days something like understanding the effects of finite precision in integer arithmetic and how it relates to fixed point DSP calcuations is probably applicable to a larger number of students!

(OK, ok, I'd be the first to admit that college courses have been dumbed down over the years as well, but this is a direct reflection of the fact that industry just doesn't _think_ they need that many engineers who DO know the 'hard core' bits...)

> These current thoughts extend to other areas:
>
> - C is more accurate than Fortran (or Basic, or what whatever)

Arbitrary statement (on the student's part).

> - Obtaining "stable" numeric results means you get the same answer if
> you run the program twice

Ditto.

> - C produces the fastest programs

There is some truth to this, perhaps if only because so much more work (as far as I can tell) has been done on C optimiziers than for other languages. Perhaps a better statement would be, "With novice programmers, C tends to produce the fastest programs."

> - if C is good then C++ is better

C++ does have a lot of nice benefits over regular old C. The last time I programmed in FORTRAN it was FORTRAN 77, but I can only imagine that FORTRAN 90 has some nice improvements over FORTRAN 77 as well. (And Delphi is purpoertedly a nice improvement to Pascal, etc...)

> - Using all the obscure C operators produces a better program

Uggh.

I was never shown that, but I do remember it being drilled into our heads that Cramer's rule was the bogosort of linear system solving -- just about the least efficient means you could possibly choose, and that it existed primarily because it can be useful to have a closed form solution to a system of equations.

Numeric analysis of linear systems is an incredibly in-depth topic, as far as I can tell. Books such as SIAM's "Numerical Linear Algebra" spends hundreds of pages going over it all.

Art Unwin wrote:
"Richard`s response to the "error" question totally ignored TOA saying they are usually the same."

Propagation dictates the take off angle that the signal actually follows regardless of what your antennas do. We made meadurements on different days so that propagation may have been different on different days. We were checking over nearly the actual paths under what might be typical conditions. Did the curtain produce louder signals? You bet!

Even though the curtain antenna had sharper vertical directivity as well as sharper horizontal directivity than the lone dipole, these were the goals of the design. Produce more signal on target to try to overcome the myriad of jammers that were trying to drown us out.

During our tests, the paths between transmitter and the receivers were the same in most cases. The width of a curtain was only about one wavelength and the dipole was immediately adjacent to the curtain. The curtain was two dipoles high, two dipoles wide and two dipoles deep as I recall. Those dipoles in front were all driven in phase. Those behind were tuned parasitic reflectors. It wasn`t unique at all. I`ve seen many since then which look very much like our curtains. They were well behaved and brought in lots of fan mail. They obviously radiated ok. The reflectors seemed to shield the villiage behind them from being drowned in radio frequency energy.

Whatever differences there may have been between the conditions imposed on the dipole and curtain, they were tuned and loaded for the same transmitted power. Received signal differences were likely due to gain in the curtain versus gain in the dipole. Averiging a large number of samples likely straightened out inevitable minor differences. I would wager our results were good enough.
My employer was satisfied and all the contractors got paid.

Best regards, Richard Harrison, KB5WZI

> interesting to see the effects on a transmitter keyed inside a shielded
> enclosure.

The MIL-STD-461E requirement for absorbed is a 10 dB return loss at 250 MHz.
I have 24" tall pyramidal foam, and that meets the requirement. As frequency
decreases, the foam essentially disappears. By 10 MHz, it has almost no
effect. The pyramidal foam is expensive, about $50 / sq ft. If you want more
return loss, you need taller pyramids; those mythical governmental labs have
had foam up to 72" tall (and the wall absorbers tend to droop a bit <g>).

A newer technique is to use ferrite tiles, especially on the floor. They are
less than a half-inch thick, and perform much better at low frequencies. And
the cost is about $100 / sq ft. I like to think of my walls and ceiling as
covered with $5 bills, and the floor carpeted with $10's.

Your anechoic chamber is never really perfect; however, it becomes "good
enough" when you run out of money.

With the dark blue pyramids and black tiles, a chamber looks like a bat
cave. One vendor decided that the new millenia needed white paint on the
foam; another vendor touts pyramids that have a 90-degree axial rotation
part way up the taper, and yet another truncates the pointy tips, telling us
that works better. It's just like the antenna game.

>> Here's what MIL-STD-461E says about conical logarithmic spiral antennas:

>> reasons.
>
> Very interesting Ed, will forward your comments to my last company. Doubt
> they will do anything tho, as they never want to spend any money. Assume
> the recomended type of antenna is a linearly polarized log periodic.

No, 461 doesn't like log periodics either, saying:

"Other linearly polarized antennas such as log periodic antennas are not to be used. It is recognized that these types of antennas have sometimes been used in the past; however, they will not necessarily produce the same results as the double ridged horn because of field variations across the antenna apertures and far field/near field issues. Uniform use of the double ridge horn is required for standardization purposes to obtain consistent results among different test facilities."

The MIL-STD defines a 104 cm rod from 10 kHz to 30 MHz, then a biconical from 30 MHz to 200 MHz, and finally, horns above there. Since pyramidal horns are only good for about an octave, a smart Navy guy added exponentially flared ridges to the horns, and came up with multi-octave horns. A typical horn for 200 MHz to 1 GHz has an aperture of about 1 meter, then another horn tries to go from 1 GHz to 18 GHz. That's a bit too far for me, as the antenna factor really climbs above about 14 GHz, so I switch to a common, non-ridged horn for 12 GHz to 18 GHz. For 18 GHz to 26 GHz and 26 GHz to 40 GHz, I use standard-gain flared horns. With a pre-selected spectrum analyzer, really good coax, and a couple of low-noise pre-amps, that lets me get comfortably below the most stringent RE102 limits.

> I remember the Singer (Was it Singer-Metrics), and using it to measure
> radiated spurious in a cow pasture at 50 m from a 1kW TMC linear
> (Canadian Marconi, Montreal). The test monopole had a cylindrical base
> with a rotary switch.

OK, just for trivia's sake. If the antenna base was cylindrical, painted grey crinkle, had a 6-position range switch and a brown bakelite top insulator, it was an Empire VA-105. But, if it was almost a cube, painted battleship grey, had a black front panel and an 8-position range switch, it was a Stoddart 92138-1 (that number is a hazy memory). Both were passive antennas. The Empire was used with the NF-105 receiver, while the Stoddart antenna was associated with the NM-22A (that's why the range switches were different, to match the ranges on their associated receivers).

1406. "Symmetrical double-L matchbox tuner"

Newsgroup: rec.radio.amateur.antenna
Date: 2005-04-26 02:01:24 UTC
From: "Joe S." <nobody@nowhere.net>
Message-ID: <d4k7d801fth@news3.newsguy.com>
Source record: 78421

On pages 47-50 of the April 2004 QST is an article about a guy who operated from the top of Mt. Kilimanjaro. On page 50 is a photo of his traveling station -- a Yaesu FT-857 with a "homebrew symmetrical double-L matchbox tuner" feeding 300-ohm TV lead-in wire to an antenna.

Where would I find details of such a tuner?

I have an old Johnson Matchbox and I suspect the homebrew tuner on page 50 is similar -- but -- I'm looking for something much smaller -- a true balanced-line tuner so I don't have to rely on a toroidal balun to feed balanced line.

Thanks.

Richard, it is now quite clear that you were not undertaking a test
referenced to a dipole. All you were doing is confirming a target area
under average conditions to ensure the language used was compatable
to the target area.....Period
More important to me is your statement that :

" Propagation dictates the take off angle that the signal actually
follows regardless of what your antennas do"

This statement seems to echo a conclusion arrived at by a regular poster
(I should call him a guru) on this group tho leaving me unconvinced.
Would you kindly point out to me what book you are extracting this
statement from so I may examine the boundaries under which that
statement is deemed correct?
Thanking you in advance

Hi All,

The method described by the paper offered above is a commonplace of
Metrology called "Reciprocity." I have calibrated precision
microphones against this method, and the error math offered is
consistent with my experience (much less the actual values offered as
examples).

As an aside, this method is also as old as the pyramids - literally.
The Egyptians planned their blocks of granite to have nearly flat
faces to within 10s of microinches using three blocks, by abrading one
against the other and then rotating their positions.

Accuracy is far more a matter of protocol or technique than it is
about a ruler (or other scale).

I don't think Richard is attempting to deny that.

His tests were not intended to measure the gain of the antenna. They were intended to answer a much more practical question: "How much stronger is the signal from the curtain array, as delivered into the BC target area, compared with using a dipole?" That's what the station owners wanted to know, and they specifically wanted that answer to <include> all the variables of antenna patterns and ionospheric propagation.

As you have correctly pointed out, in any environment except free space, that number is not the same as the antenna gain in dBd. Anybody who has thought about it is aware of the problem, and that clearly includes Richard.

Everybody agrees with you, so you can stop banging on that open door.

Hi Joel,

I skipped this groaner the first time through. You could program in
almost any language to the same speed of performance if you simply
focused on the 5% bottleneck and coded it in assembler. Nearly every
"optimizer" consists of saving a lazy programmer's bacon when they
sloppily write poor control structures and assignment statements. It
should be called a de-babelizer.

Just tune the highest frequency antenna first
and then work down.....

It's much easier if you start low, and go up...
If you have interaction, it's almost always a
"higher" band. So if you start low, you'll only
have to do each, once...Going the other way,
can have you chasing your tail after a while...
IE: the higher bands will usually change when
adding the lower bands if the wires couple...
Rarely the case, the other way around.
I've used parallel dipoles for years...
My favorite config for everyday use dipoles.
Once, even had paralleled turnstiles for 80/40 on
one coax...
At the present, I have 160/80/40 on one coax..
To make a noticable difference over a dipole,
you'll need to get some serious gain...If you don't
get at least 4-5 db over the dipole, I hardly think it's
worth the hassle...That G5RV would have appx 2-3
db broadside over a 1/2 dipole, assuming you aren't
losing power feeding it...:(I agree with Reg, I'd either
run coax, or ladder line, but not both....To me , running
both is an exercise in sillyness...But to many, their own...
Ladder line, if you have a tuner, or coax, if single band,
or a remote tuner, etc...

.....
Is it true, though, that when the ladderline/windowline gets wet it
negatively impacts the efficiency of the transmission line?
.....

Depends on the ladder line, and whats in between the wires...
300 ohm line can be bad, and also other lines that have no
"windows", etc between the wires...Supposably, the "windowed"
ladder line is less effected by rain. Open ladder line with insulators,

almost no impact at all...I've seen 300 ohm line turn near useless
on UHF when raining hard. I used it to a large UHF TV antenna I
used to receive ATV. Great when dry, but get it wet.....:(

Hi Ian

Yep sorry about that. Its a spam reduction exercise. Use bcnuup instead of bcnntp and you'll get me.

At work we use a mix of Auslig/Geoscience Australia 9 arcsecond and the SRTM 3 arcsecond data for our RF coverage stuff. The 9 arcsecond stuff costs $$ from http://www.ga.gov.au but the SRTM stuff is free - ftp://e0mss21u.ecs.nasa.gov. It does however need void removal. There are a few other ASCII datasets of higher resolution available from GA but they tend to be restricted to populated areas. If your VK4 mate wants void removed SRTM data get back to me and I'll send them a CD.

Geoscience has free downloads of 1:250K topo maps but anything of a higher resolution also costs.

If you are after only NSW data there is a nifty map portal http://maps.nsw.gov.au that allows you to look at very high res topo information.

I dont know if NED data is available for Australia. There may be some conversion utility to use SRTM data but I havent checked... There are quite a few apps out there that do conversions. Have a look at Blackart (http://www.terrainmap.com) and LandSerf.

Sorry I cant give an exact answer. I havent looked at HFTA at all.

Cheers Bob Vk2YQA

Your arguments arise from trying to compare two different test goals, e.g., accurately measuring the free space az/el radiation patterns of an antenna itself, versus how those radiation patterns may perform in a particular application (height above ground, ground characteristics, ionospheric propagation characteristics, reflection sources, target coverage zone, etc).

Classic antenna test ranges are designed to measure the az/el radiation patterns of antennas themselves, independent of their environment. What that radiation will provide in terms of a desired "coverage" result is another matter, and is the responsibility of the RF system designer -- not the antenna test range.

Thanks again Ed. From everyone of your posts I learn something new.

> The MIL-STD-461E requirement for absorbed is a 10 dB return loss at 250
> MHz.

Assume you would test the chamber return loss with a tuned dipole having free space return loss >>10dB. i.e. some physically realizable antenna with a return loss of 40 dB at the test frequency. I suppose, with an inductivly loaded dipole, you could test the return loss of a 3 m chamber down to 30 MHz. There were some questions raised about possible reflections in the 3 m chamber due to imperfections in the installation of the pyramidal foam. I tried sweeping from 1 to 10 GHz with the log spiral antenna, coupling to a non-standard antenna, and performing an inverse FFT on the network analyzer data to generate a time domain plot. I had very little success in actually seeing reflections. For best resolution the ideal would have been to sweep from 30 MHz to 20 GHz with two wide band antennas, but the company did not want to spend the money for any new antennas. What I am thinking is that careful return loss measurements may have shown if any reflections were present.

> I have 24" tall pyramidal foam, and that meets the requirement. As
> frequency decreases, the foam essentially disappears. By 10 MHz, it has

I think we were using 12" pyramdal foam, even on the floor, with inverted foam to provide a walking area.

> The pyramidal foam is expensive, about $50 / sq ft. If you want more
> return loss, you need taller pyramids; those mythical governmental labs

> <g>).

With a 3m chamber, anything greater than 12" is not really practical.

I have heard of the ferrite floor tiles, and are probably a much better
solution than inverted pyamids fitted into the floor mounted pyramids.
